the lighting of the outlying districts of the town; but the ratepayers should know that the Commissioners were not to blame for seeming negligence, because they had waited to see if the builders of the new properties in the district referred to would put down proper footpaths before they erected lamps. It was a pity, he said, that the Commissioners had not more authority in the matter. Some discussion took place on the subject; and the opinion of the meeting was that the builders were not fulfilling their duty in erecting their tenements without forming proper roadways and pavements. It was agreed that temporary lighting should be provided during the forthcoming winter months.

A Valuation Appeal Court for the Upper Ward of Renfrewshire was held in Paisley last Monday. One of the appeals brought under consideration was made on behalf of the Pollokshaws Gas Company, against their gas-works being put on the valuation roll at £586. Mr. Gillies asked that the valuation should be fixed at £300; and the Company would not be put to the trouble of coming before the Court year after year. The true value, he held, was to take what the subjects might fairly be expected to let for one year with another; and this could best be ascertained by taking a percentage of the cost of buildings and the plant, instead of the profits made, which depended greatly on the price of the raw material and of the gas consumed. After considering the case, the Court decided to reduce the valuation to £500. On the application of Mr. Gillies, a case was granted.

On the same day, at an Appeal Court held at Dunoon, an appeal was heard from the Dunoon Gas Company. The Directors asked that the valuation of their works should be reduced from £600 to £450. Mr. Munro, who represented the Company, said that Mr. Maxtone, the Assessor, had increased the valuation of the gas-works by £150; and he was very much astonished at it, because he thought the Court last year, when an appeal was heard, had finally disposed of the case. The Court were then unanimous in their decision that the valuation of the works should be £450. There was no change in the circumstances; and yet Mr. Maxtone proposed to increase the amount by £150. If things went on in this way it would cripple the Company altogether. Mr. Maxtone replied that last year the Company pleaded so much poverty that they quite overcame him; and £100 was taken off. This year they wanted £150. Acting on his basis of calculation, Mr. Maxtone showed that the valuation of the works came to £600; and taking it on the principle laid down by Lord Fraser—viz., 8½ per cent. on the cost of the works—the valuation came to £700. Mr. Munro pointed out that in certain large towns the gas-works were only assessed on about £300. In support of his case the Assessor used a somewhat unusual argument—viz., that the increased valuation would be better for the Company when they came to hand over the gas-works to the Corporation. It naturally excited some laughter; and Provost Lyall, who was present, remarked that it would be some time before the Corporation would be prepared to buy the works. Eventually the Court restricted the valuation to £550; and Mr. Munro asked a case for appeal, which was granted.

The Glasgow pig-iron warrant market has again been very strong this week. Scotch warrants advanced in price from 41s. 7d. per ton cash on Monday to 42s. 7d. yesterday afternoon; the close being 42s. 6d. cash buyers. The price of hematite iron fluctuated between 45s. and 45s. 9½d. per ton, and in Cleveland iron the range was between 34s. 3d. and 34s. 9½d. per ton cash; the close being respectively, 45s. 8d. and 34s. 9d. cash buyers. A further advance has taken place in the prices of most of the Scotch special brands. Some considerable sales of Scotch pig iron have been made during the week on American account.

A further improvement in the local coal trade is reported, more especially in the export department. Prices all round are firming up; and to such an extent that the miners are beginning to put in a claim for an advance of wages.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Sept. 15.

Sulphate of Ammonia.—The scanty orders during the present week make one fearful lest the season's requirements should all be completed. The lateness of the harvest gave hopes of the demand coming later, yet in full vigour; but it appears now almost as if we were to be disappointed. From what can be gathered generally from consumers, they are all ready to buy forward, but only at what they term cheap prices; while in the event of the market remaining steady, they express determination to wait until the time of absolute necessity. Producers on the other hand are indifferent about making forward sales, as no advance on to-day's values can be obtained, and the great firmness of nitrate supports them in their views that sulphate cannot permanently be lower. The future seems, therefore very uncertain; and it remains to be seen how the course of the market will shape, when the production, which will be increasing again shortly, comes to be disposed of. There is very little alteration in the figures; and the market remains steady at £11 5s. to £11 7s. 6d., according to ports and delivery.

LONDON, Sept. 15.

Tar Products remain at much the same as last week's prices. Benzol, perhaps, is scarcely so strong; but anthracene and the other articles are in good demand. Prices may be taken as follows:—Tar, according to position, 17s. 6d. to 22s. 6d. per ton. Benzol, 90 per cent., 3s. per gallon; 50 per cent., 2s. 4½d. Toluol, 1s. 9d. per gallon. Solvent naphtha, 1s. 2d. per gallon. Crude naphtha, 30 per cent., 1s. per gallon. Light oil, 3d. per gallon. Creosote, 2d. per gallon. Pitch, 12s. to 13s. 6d. per ton. Carbolic acid (crude), 3s. 4d. per gallon. Cresylic acid, 9d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 6d. per unit; "B" quality, 1s. 3d.

Ammonia Products.—Sulphate of ammonia is firmer; and no doubt, with the sharp rise which has taken effect in nitrate of soda, sulphate will derive some substantial advantage. Prices: Sulphate of ammonia, £11 7s. 6d. to £11 10s., less discount. Gas liquor (5° Twaddell), 7s. 6d. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 1½d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £27. Sal-ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, Sept. 15.]

Sulphate of Ammonia.—The sulphate of ammonia market is very quiet indeed; and so far as present delivery is concerned, the demand is dead—the few parcels changing hands being bought by dealers in fulfilment of previous sales made by them. To-day's price at Hull and Leith ranges from £11 5s. to £11 6s. 3d.; and although Beckett is again quoted at £11 5s., London outside makes have fallen to £11 5s. also.

Tar Products.—The benzol market remains much in the same condition as it stood last week. Perhaps, if any change has occurred, it is in the shape of increased steadiness in 90's benzol, which may to-day be quoted at 3s., and 2s. 4d. to 2s. 5d. for 50/90's. There is still a good demand for solvent naphtha and creosote for Lucigen light purposes. The anthracene market is firm; and 1s. 5d. to 1s. 6d. may be quoted as to-day's value for "A" quality in London. "B" quality is selling at 1s. 2d. to 1s. 3d. The pitch market remains as stated in our last week's report; there being no change in this direction.

OIL LIGHTING IN KENT.—The local authorities of Northfleet have had a similar experience with their contractors for lighting the public lamps with oil to that of the Erith Local Board, referred to elsewhere; and complaints as to bad lights through neglect on the part of the trimmers have of late been very prevalent. The Northfleet authorities have decided to give notice to the contractors that if the lighting is not properly and efficiently carried out, fines, according to the terms of the contract, will be enforced. The local authority of Snodland, owing to a misunderstanding with the Gas Company, have commenced to light with oil the streets under their control.

THE PUBLIC LIGHTING OF MARLBOROUGH.—At a recent meeting of the Marlborough Town Council, a letter was read from the Gas Company, submitting proposals for the lighting of the lamps in the borough all the year round, from one hour after sunset to one hour before sunrise, for 70s. per lamp per annum, or else for the adoption of the average meter system. The Town Clerk submitted a statement showing the comparative expenses and hours of lighting in various towns in the district, from which it appears that the rate at Marlborough (4s. 7d. per 1000 feet) is about the average. The present cost per lamp in Marlborough was stated to be £3 7s. 6d. per annum. The Council eventually resolved to adopt the average meter system.

THE TESTING OF THE OLDHAM GAS.—At a meeting of the Oldham Corporation Gas Committee held last Wednesday, the Chairman (Alderman Hall) reported that Mr. Estcourt, the Borough Analyst, who had been appointed by the Committee to make an independent inspection of the gas, had recently tested it at the Oldham, Higginsshaw, and Royton stations, and that he had found the illuminating power was as follows:—Oldham, 19·10 candles; Higginsshaw, 20 candles. At Royton the apparatus was being repaired. The gas at all the stations was quite free from sulphuretted hydrogen. At Oldham and Royton it was free from ammonia; but at Higginsshaw the gas was found to contain a small trace. A discussion ensued as to the advisability of retaining Mr. Estcourt's services. It was stated that the engagement entered into was in April last year; Mr. Estcourt being appointed to make two tests in the year, and to receive 20 guineas for his services; and it was added that he had made the last test entirely on his own responsibility. The Chairman said that, though personally he was in favour of the project when Mr. Estcourt was appointed, he did not now think that the Committee had derived any benefit from it. He moved that the Town Clerk write Mr. Estcourt that his engagement had expired; and this was agreed to.

SULPHURETTED HYDROGEN.—None on any occasion.

PRESSURE.—In excess on all occasions.

Note.—The standard illuminating power for common gas in the Metropolis is 16 sperm candles, and for cannel gas 20 sperm candles. Sulphur not to exceed 17 grains in 100 cubic feet of gas; ammonia not to exceed 4 grains in 100 cubic feet of gas. Pressure between sunset and midnight to be equal to a column of 1 inch of water; between midnight and sunset, 6-10ths of an inch.

GWYNNE & BEALE'S PATENT GAS EXHAUSTERS AND ENGINES.

PLEASE ADDRESS IN FULL—

GWYNNE & CO.,ADDRESS FOR TELEGRAMS:
"GWYNNEGRAM LONDON."HYDRAULIC AND GAS ENGINEERS, ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C., ENGLAND.
TELEPHONE No. 2688.

Thirty-three Medals at all the Great International Exhibitions have been awarded to GWYNNE & Co. for Gas Exhausters, &c.

Only Medal at the Liverpool International Exhibition, 1886, for Centrifugal Pumping Engines.

They have never sought to make price the chief consideration, but to produce Machinery of the very highest quality.

The result is that in every instance their work is giving the fullest satisfaction.

They have completed Exhausters to the extent of 24,000,000 cubic feet passed per hour, which are giving unqualified satisfaction in work, and can be referred to.

ONLY 75 REVOLUTIONS PER MINUTE.

The above Engraving shows Two Engines driving Four GWYNNE & CO.'S PATENT NON-FLUCTUATING EXHAUSTERS, to pass 200,000 cubic feet per hour (without the slightest oscillation), at the EFFINGHAM STREET GAS-WORKS, SHEFFIELD.

OXIDE OF IRON.

THE Gas Purification and Chemical Company, Limited, advise their friends that their only representatives for the Sale of Oxide are Mr. Andrew Stephenson and such Sub-Agents as may be accredited from the Head Office. They further state that the royalties possessed by them extend over an area of more than 350,000 acres, and are held for a long term of years. They employ their own overseers and labourers, and there are no intermediate profits between them and the consumer.

Address 161 to 163, Palmerston Buildings, Old Broad Street, LONDON, E.O.

JOHN WM. O'NEILL,
Managing Director.

ANDREW STEPHENSON, Agent for the Gas Purification and Chemical Company, Limited, 168, Palmerston Buildings, Old Broad Street, LONDON, E.O.

CANNEL COAL, &c.

JOHN ROMANS & SON, EDINBURGH. Gas Engineers, supply all the most approved SCOTTISH CANNELS; also FIRE-CLAY GOODS, CAST-IRON PIPES, and other APPARATUS for GAS AND WATER WORKS.

Prices, &c., will be forwarded on application to No. 80, St. Andrew Square, EDINBURGH, } SCOTLAND.
No. 64, BERNARD STREET, LEITH,

TIMMIS & CO., of STOURBRIDGE

Make only the best quality of FIRE-CLAY RETORTS, BRICKS, TILES, & LUMPS. Also SPECIAL SILICA BRICKS, to stand great heats. All descriptions kept in Stock.

For Prices apply to JAMES LAWRIE and Co, 68, Old Broad Street, E.C., Sole Agents for London and District. Telegraphic Address: "EIRWAL, LONDON."

ALEX. WRIGHT & Co., 55, 55a, and 56,

MILBANK STREET, LONDON, S.W.
[Telegraphic Address: "PRECISION LONDON."] Makers of Wet and Dry Gas-Meters, Station Meters and Governors, Photometers, and Gas-Testing Apparatus, Test Gas-holders and Meters, Registering and other Gauges, &c., &c.

* See Advertisement on Page 111. of the Wrapper of last week's issue.

W. C. HOLMES & Co., Huddersfield,

AND 80, CANNON STREET, LONDON. Contractors for Gas-Works complete, Makers of Gas-holders, Purifiers, Scrubbers, Condensers, Retort Fittings, &c., Improved Valves, Engines, and Exhausters. A so for Collingwood's Regenerative Retort-Settings.

* See Advertisement p. 538 of this week's issue. Cablegrams: "Ignitor London." Telegrams: "Holmes Huddersfield."

IRISH BOG ORE OXIDE OF IRON.

GAS PURIFICATION.

BALE, BAKER, & CO., direct Importers from Ireland. Sample and Price on application. Spent Oxide and Sulphate of Ammonia purchased. 120 and 121, NEWCASTLE STREET, LONDON, E.C.

TUBES.

FOR Gas, Steam, and Water; Galvanized White Enamelled, and Hydraulic Tubes and Coils JOHN SPENCER, Globe Tube Works, WEDNESBURY, and 14, Great St. Thomas Apostle, LONDON.

SULPHURIC ACID.

JOHN NICHOLSON & SONS, Chemical Works, LEEDS, specially produce this ACID for making SULPHATE OF AMMONIA of high quality and colour. Highest References and all particulars supplied on application.

SULPHURIC ACID.

HUGH WALLACE & CO., Chemical Manufacturers (the old-established firm), supply the above, which is specially adapted for making White Sulphate of Ammonia. The latter purchased in any quantities at highest market prices, or contracts for the year. For price and terms apply Botolph House, Eastcheap, LONDON, E.O.

Can be made, when desired, on their New Patent principle to pass Gas without the slightest oscillation or variation in pressure.

NO OTHER MAKER CAN DO THIS.

GAS VALVES, VACUUM GOVERNORS, REGULATORS, PUMPS, &c., &c.

Catalogues and Testimonials on application at the above address.

be different; and then the Local Authority concerned would find themselves under the burden of serious responsibility.

THE IMPORTANCE OF LITTLE INVENTIONS.

THE publication in our columns last week of a description of a patented device for the speedy and economical extraction of cast-iron main-pipes from the lines in which they lie in the ground, reminds one of the multiplicity of small inventions whereby the work of making and distributing gas has been improved and facilitated of late years. This is a subject that might very well be worked up into a paper for a District Association of Gas Managers, by anybody who would take the trouble to compare the tools and processes in use now with those available (say) twenty years ago. We deliberately exclude from this review all changes in manufacturing processes which ordinarily form subjects for papers and memoirs, and confine our attention to the small details that nobody would think of bringing into notice alone. How many and various are the novelties of this kind that distinguish a well-equipped gas-works of to-day from the same establishment as conducted by the worthy men of the past generation! We published an article some time ago upon the importance of saving the "drop of solder" in manufacture; showing that all industrial progress is due to these intrinsically insignificant advances. A neat method of fastening a retort-lid, a device for taking up the wear of a hinge or a bearing, a trifling alteration of a governor valve—all these things mean progress of the most substantial kind. If one goes into a warehouse and looks over an assortment of fittings, how often does it happen that the attention is caught by something which is an evident improvement upon a well-known pattern; and we are told that it is a little invention just introduced by someone who knows the requirements of the trade! There is nothing theatrical about these small advances; they do not revolutionize anything; and the benefit derivable from any individual one of the class may be very slight. In the mass, however, they tell upon the art or industry in which they are used. It is often said—so often that the saying is sadly threadbare—that he is a benefactor of his species who makes two blades of grass grow where one grew before. If this time-worn old saw is used to illustrate the value of what Sir Frederick Bramwell has recently called the "next-to nothing," it fails; because to double the production of forage for a given area is not a small thing, but a great feat. To drive home our meaning, we should say that the man who can increase the length of a blade of grass by one-sixteenth of an inch is a benefactor to the world. He has thereby laid the foundation for a possible new variety of grass, more productive than the old, which may make all the difference between wealth and ruin to the future agriculturist. So in machinery, the inventor of a new and improved piece of detail, however small, so that it serves its purpose better than that which went before, is a true leader in industrial art.

Water and Sanitary Affairs.

As a rule, *ex parte* statements are to be distrusted; and probably it would be rash to make an exception in favour of the vituperative remarks of the gentleman who a day or two ago attacked the Chelsea Water Company at the Westminster Police Court. The applicant worked himself up to a high pitch of indignation not only against the Chelsea Company, but against the Metropolitan Water Companies in general. He complained of "a most iniquitous and high-handed proceeding" in the particular case referred to; declared that he had been treated with scant courtesy at the Company's office; and inveighed in general terms against "these great 'monopolist Companies,' who, it was suggested, did what they pleased with the down-trodden and oppressed consumer. Such is the formidable indictment which was preferred before Mr. Biron, Q.C., last week. It is not the first time the London Water Companies have been violently scolded in a Metropolitan Police Court; and we doubt not that the same thing will at intervals occur again. When some irate landlord or consumer airs his exaggerated grievances in the presence of a Police Magistrate, the reporters eagerly jot down his florid sentences; and in due course the dailies have recourse to the familiar head-line of "The Water Companies and the 'Public.'" Doubtless, now and again, the Companies are to blame. It is not given to mortals, or to companies, to be invariably in the right; but experience undoubtedly shows

that, in nine cases out of ten, the *ex parte* statements of the grievance-mongers will not bear the test of full and impartial investigation. There are two sides to every question, even where a Water Company are concerned; and we should be by no means surprised if a very different light could be thrown upon the particular facts, if facts they were, which were stated at the Westminster Police Court in the absence of the Chelsea Company's officials. In the meantime all this noisy flourish is calculated to deceive the public and to unfairly prejudice the Company whose conduct was complained of; the more so as the applicant, after pouring out the vials of his wrath, coolly stated that he could not attend again, as he was about to go to Scotland. This certainly looked as if he were not labouring under any abiding sense of injustice, although he gladly availed himself of an opportunity of blowing off the steam engendered by his dispute with the officials of the Water Company. What the applicant wanted indeed, if he could get it, was a peremptory order, based on his own version of what had taken place, for the Company to reinstate the pipe which they had disconnected. Of course, Mr. Biron had no power to comply with such an application, though apparently, and perhaps naturally, his sympathies were with the applicant. The learned Magistrate, whose somewhat hasty exposition of the Married Women's Property Act called forth some criticism on a recent occasion, paused before expressing any definite opinion as to the rights of the Company on the one hand and of the consumer on the other. Discretion prevailed; and Mr. Biron declined in this instance to undertake off-hand the interpretation of the law in regard to the matter before him. We think his Worship's reticence was commendable, for our Metropolitan Magistrates are sometimes hurried into rash statements, and are too generally expected to act as the "guide, philosopher, 'and friend'" of all sorts of applicants on every conceivable subject. Nevertheless, the law, so far as it is to be found in the Water-Works Clauses Act, 1847 (which some of our indignant contemporaries convert into the Water Companies Consolidation Act), is tolerably plain and intelligible. Section 74 of the Act provides that if the person supplied with water, and liable to pay for it, neglect to pay the rate at any of the prescribed times of payment, the flow of water into the premises in respect of which the rate is payable may be stopped by cutting off the pipe to such premises, or by such means as "the undertakers" may think fit. Section 70 enacts that the rates shall be paid quarterly; and that the first payment shall be made "at the time when the pipe by which the 'water is supplied is made to communicate with the pipes of 'the undertakers, or at the time when the agreement to take 'the water from the undertakers is made.'" These provisions are simple enough, and are necessary in the general interests of the public as well as of the Companies. Of the special powers possessed by the Chelsea Company under their own Act, we will not undertake to speak. We are not expressing any opinion on the particular case which was brought to Mr. Biron's notice, though, as we have indicated, we should expect to find that the powers of the Company have not in reality been exceeded.

The report of the Gas and Water Committee of the Corporation on the question of the constant supply, to which we made reference some weeks ago, came before the Court of Common Council on Thursday, and gave rise to a discussion of which a full account is given in another part of our columns. The Corporation have seen fit to adopt this somewhat remarkable report, whereby the City is made to plead that a constant supply of water is a luxury in which it cannot afford to indulge. Perhaps it may be suggested that water is not a popular beverage with the City magnates, who are familiar with something of a more exalted character than *aqua pura* at their civic banquets. A constant supply of champagne or turtle soup would perhaps be more keenly appreciated. But there are people, nevertheless, within the City boundary, who have a desire for something which they deem more convenient and satisfactory than an intermittent supply of water. It happens, however, that what may be termed an active demand is small. Out of fourteen parishes which have spoken their minds on the subject, ten are in favour of the constant supply, and four are against it. There remain 98 who say nothing. So far as we can remember, the spread of the constant supply, comprehending now more than one-half the houses in the districts of the Metropolitan Water Companies, has been brought about by the Companies and the consumers irrespective of the Local Authorities. Also in regard to the hydrants, excepting the City proper, the extent to which

these have been introduced is mainly due to the initiative of the Water Companies. In their efforts to extend the constant service, the Companies have frequently to encounter obstacles where they might rather have looked for assistance. Some of the Authorities, in days that are now happily gone by, were accustomed to argue that hydrants would be superfluous unless they rendered fire-engines unnecessary. So an idea now prevails in many quarters that, where there is a constant supply, there ought not to be any need for storage cisterns. The East London Company, in the interests of the consumer, and, as we believe, in accordance with the law, require that there shall be a storage cistern as well as a waste-preventer. This is looked upon by some misguided people as a gross piece of tyranny, and the notion is shared by Mr. Lushington, the Magistrate at the Thames Police Court, who has just decided that a waste-preventer holding two gallons of water is all that the law requires. Certainly it is not all that the consumer needs, as recent events have proved in the East London district. But the decision of the Magistrate goes against the Company, who will now have to carry the case to a Superior Court, where it is to be hoped a little common sense will prevail.

The sewage scheme of the Manchester Corporation forms the subject of an inquiry which is being conducted in the Town Hall, Manchester, by Mr. S. J. Smith, C.E., one of the Inspectors of the Local Government Board. The opposition presents a formidable front, if we may estimate its strength by the array of Counsel who appear on behalf of the objecting parties. The opponents consist of numerous local authorities outside the city area; and a large number of persons owning or occupying property in the neighbourhood of the proposed outfall works. The application to the Local Government Board is for power to borrow £450,000 for a scheme of sewerage and sewage disposal, and £40,000 for the purchase of land. The sewage of the city is to be gathered up in two intercepting sewers, converging into one at the city boundary, and proceeding thence to a point four miles distant, where the sewage is to be treated chemically, so as to throw down the matters in suspension. The liquid is then to be filtered through 60 acres of land, on the plan of intermittent downward filtration; the effluent passing into the River Irwell, and thence into the Manchester Ship Canal. The effluent must be of a character to satisfy the Canal Company; and an agreement has been entered into for the purpose. The area of the City of Manchester is nearly 6000 acres; and the population, 378,000. The present daily water supply is thirteen gallons per head for domestic, and seven gallons for trade purposes. There are 18,800 water-closets, 66,000 dry-earth closets, and no cesspools. The sewerage plan is devised for a population of 500,000; and a daily water supply of 44 gallons per head. The rainfall is 35 inches per annum, and the proposed sewers are estimated to carry off a maximum of 100,254,000 gallons per day. At the outfall works, the sewage will pass through a series of tanks; precipitation being effected by means of lime and sulphate of alumina, or "the best known precipitant." There is to be an overflow, by means of which, if necessary, the whole of the effluent could be passed direct into the Ship Canal. Mr. Allison, the City Surveyor, says he has designed the sewers of such dimensions that they would suffice for the requirements of Manchester, even if the present pail system were to be done away with and superseded by water-closets. The daily volume of wet sludge produced by the precipitation process is reckoned at 120 tons, to be dried down in four days to 25 tons. Such are the leading features of a plan which appears to possess considerable dimensions, though it has to encounter the objection of being too restricted, as it ignores certain outlying localities contiguous to the route of the outfall sewer. There is a "Greater Manchester" which pleads to be included. There is also a demur on the customary plea of nuisance, and it is urged as a hard matter that people who go out of Manchester in pursuit of health should afterwards have the sewage brought to their doors. Another objection has reference to the filtering area, which is declared to be too small. This part of the question is obviously affected by the efficiency of the chemical process which precedes the action of the filter-beds. The City Surveyor does not believe that any more land is, or will be, necessary. He rather expects that four or five years hence "chemical science will be so far advanced" that the Corporation will have no use even for the 60 acres. Dr. Frankland has also given evidence in support of the scheme, and believes the area for the filter-beds to be ample. Concerning the effluent, he says it

would not be pure enough to drink, or so pure as he should prescribe for an effluent that would be turned into a river from which towns took their water; but it would be sufficiently purified for the purpose for which it was to be used. We observe that Dr. Frankland speaks as if the whole 95 acres of land at the works would be available for filter-beds. According to the Coventry ratio, to which he makes reference, 60 acres would about suffice for the present population of Manchester, leaving no margin for increase. In cross-examination, Dr. Frankland seems to have the 60 acres in view, and says it would, of course, be better if the Corporation had a larger area at their disposal. With respect to irrigation, it is said that no such scheme is practicable for Manchester. The issue of the inquiry will be awaited with much interest. It is a great "sewage fight." Dr. Pankhurst, who is one of the opposing Counsel, declares himself ready to prove that, while the drainage scheme of the Corporation is "an admirable one," the plan proposed for the disposal of the sewage involves "a terrible mistake." Officials, medical and otherwise, from Bradford, Coventry, Leeds, and Bolton, have given evidence in defence of the plan for the treatment of the sewage, founded on their local experience. Mr. James Mansergh, C.E., approves of the entire project—the sewers, the outfall, and the sewage works. The line of cross-examination with regard to these witnesses suggests that the sludge would be likely to prove offensive to the neighbourhood, Dr. Charles Meymott Tidy appeared on behalf of the Corporation, and declared that the plan they were seeking to adopt would be "of enormous public benefit." The case for the Corporation closed on Saturday, and the examination of local witnesses in opposition has now commenced.

MR. HELPS' SYSTEM OF PIPE EXTRACTION.—In the article in the JOURNAL last week (p. 508) describing the appliance invented by Mr. J. W. Helps, Engineer of the Croydon Gas Company, for extracting cast-iron gas and water mains from the lines in which they lie in the trenches, it was by inadvertence omitted to be stated that the system has been patented, and therefore cannot be used without Mr. Helps's authority.

THE MANAGEMENT OF THE LEEDS GAS-WORKS.—At a meeting of the Gas Committee of the Leeds Corporation last Thursday, the resignation of Mr. E. J. Lloyd, Resident Engineer at the York Street Gas-Works, who, as announced last week, has been appointed Engineer and Manager of the Avon Street works of the Bristol Gas Company, was accepted. Mr. Townsley, of the Meadow Lane works, has been appointed to the position vacated by Mr. Lloyd.

PRESENTATION TO MR. G. GARNETT, M. INST. C.E.—On Monday afternoon last week, the Mayor of Ryde (Mr. R. Colenutt), accompanied by the Town Clerk (Mr. J. W. Fardell) and several members of the municipal body, waited on Mr. George Garnett, M. Inst. C.E., Engineer and Secretary of the Ryde Gas Company, at his residence, for the purpose of presenting him with an illuminated address on behalf of the Corporation. The Mayor, in making the presentation, referred to the many good works with which Mr. Garnett had been associated in connection with the town, and especially to his generosity in giving the Corporation a handsome mace—a gift which he was sure the whole town very much appreciated. He expressed the hope that Mr. and Mrs. Garnett might live for many years to look upon the testimonial which it was his pleasure to present. Mr. Garnett thanked the Mayor and the representatives of the Corporation, and expressed his high appreciation of their gift, which he said he should show to his friends with great pleasure. He hoped that when looking thereon, others might be induced to follow his example. If they did so, they would find the truth of the Scriptural adage that it was more blessed to give than to receive. The address, which is a beautiful work of art, was engrossed by one of the staff in the Borough Surveyor's office. Its presentation was in virtue of a resolution passed by the Council on the 10th of July last, just after the gift of the mace by Mr. Garnett. It sets forth that it is a testimony of the appreciation by the Corporation of the public spirit with which Mr. Garnett had helped every movement "having for its object the dignity and prosperity of the borough." The address, which is sealed with the borough seal, and signed by the Mayor and Town Clerk, is surmounted by the borough arms, and has a capital representation of the mace introduced amongst the other artistic embellishments. Referring to the presentation, the *Isle of Wight County Press* last Saturday said: "Very few citizens can show so good a record of public service as Mr. George Garnett. He was one of the originators of the Municipality of Ryde; and now he has been the means, directly and indirectly, of equipping its Corporation with a chain of office, a mace, and a loving cup. . . . As Chairman of the Ryde School Board, too, he has done a splendid work. Generous in all public matters, he has privately done much good. The whole town will cordially re-echo the words of the Mayor of Ryde in presenting the richly-deserved testimonial from the Corporation, and will wish him many a year of life in which to look back with satisfaction upon his work in Ryde, and to be the centre from which other beneficent deeds may arise."

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 562.)

BUSINESS on the Stock Exchange during the past week has been active; although the happening of Jewish holidays in the course of it made things quieter for a time. The general tendency, after a little hesitation at first, has been good; and most descriptions have moved upwards except the Funds, which have been affected by dearer money. Money has been in demand, and the market is firm. A further rise in the rate would not come altogether as a surprise; but it will depend on the course of financial affairs between now and next Thursday. The Gas market has been rather quieter. But few changes have occurred in the quotations; and these are somewhat irregular. The tendency of the Metropolitan Companies has been easier. Gaslight "A" opened steady on Monday, but gradually fell away, and closed at its worst on Saturday; the final mark being 252. In South Metropolitan, the "A" and "C" have not been dealt in at all; but there have been a few transactions in "B." Prices have varied very little; but the quotation is 2 lower. A couple of transactions in Commercial old were all; and the quotation is unchanged. In the Suburban and Provincial Companies, business has been very quiet—except Alliance and Dublin, which has met with more attention, and changed hands at good figures; the time for payment of the dividend being near. A transaction in Crystal Palace 7 per cents., which is a rarity, was marked at 152. This would be equivalent to about 217 for the 10 per cents., or rather better than the nominal quotation. Of the foreign undertakings, Imperial Continental is quoted 1 higher; but the transactions marked were at no better prices than the week before. Continental Union preference is also 1 better, and both Bombay issues have risen $\frac{1}{4}$. The Ottoman Company meet to-day to declare a dividend at the old rate of 7 per cent. There has been more animation in Water; and several further improvements have been made in the quotations. The advance in Lambeth is most noticeable. The 10 per cent. shares are now almost treading on the heels of New River, which used to lead the rest by a considerable distance. Why Kent should be left so far behind the others is a mystery, as it is by no means the worst or the worst-managed Company.

The daily operations were: Quiet business in Gas on Monday; but the prices were extremely good. Water was pretty active, with a rise of 2 in New River, and 1 each in Kent and Lambeth. On Tuesday, Imperial Continental was the busiest of the Gas issues; little else being touched. Continental Union preference rose 1. Water was quieter, but very firm; and West Middlesex rose 1. Wednesday's Gas business was only moderate, and offered nothing to remark but a fall of 2 in South Metropolitan "B." Water was dull and unchanged. On Thursday, business in Gas was again limited. Imperial Continental advanced 1. Water as before. On Friday, there was business done in several Gas issues; but very little in any one. Bombays rose $\frac{1}{4}$. Water was more active, and good prices were marked. Southwark ordinary improved 1. Gas was quiet on Saturday, with a weak tendency—especially in Gaslight "A," which receded 1. Nothing at all was done in Water.

ELECTRIC LIGHTING MEMORANDA.

PROFESSOR FORBES UPON THE WESTINGHOUSE SYSTEM—THE ELECTRIC LIGHT IN ITS PLACE—THE PROPOSED ELECTRIC LIGHTING SCHEME FOR BIRMINGHAM.

THE communication from Professor George Forbes, F.R.S., to the Mechanical Section of the British Association, upon "Electric Lighting in America," was looked forward to with considerable interest. This was fully understood by Professor Forbes himself; and in introducing his subject, he assumed the duty of a scientific reporter upon the progress of central-station lighting in the United States during the past four years, since the Association visited America. He went on to remark that, the moment one lands in the States, one is struck by the popularity of electric lighting; and he says that this impression is maintained after leaving the great cities, and making the acquaintance of out-of-the-way towns. Of late years, however, the greatest progress that has been made in central-station lighting in America is the work of Mr. Westinghouse, who has made the Gaulard and Gibbs system a commercial success. As an illustration of the extent to which Mr. Westinghouse's electric lighting business has expanded, Professor Forbes states that he has at the present moment set up 110 complete central stations, with 191,000 lamps. Professor Forbes declares that he is no blind worshipper of American enterprise in general, or of Mr. Westinghouse's methods in particular. He admits that much of the best electrical plant and machinery are English; and does not think that the Electric Lighting Act, although he calls it iniquitous, is altogether to blame for the stagnation of the electric lighting business in this country. He is rather inclined to think that the cause of the progress of electric lighting with inferior appliances in the States is to be found in the spread of "technical instruction among the moneyed classes." This is a high-flying explanation indeed. People more awake to small considerations than Professor Forbes appears to be, might be inclined to add to this explanation a reference to prices of gas in America, and to the forbearance of the public with regard to the quality of the lighting. Capitalists have helped electric lighting speculators in this country, to their cost; but with little of the encouragement they appear in some instances to have received in

the States. However, to return to Professor Forbes's story. He gives due praise to the American electricians, and especially to the Westinghouse Company, for their forethought in manufacturing all their plant and machinery according to predetermined types in regular sizes; so that every part is interchangeable, and nothing has to be specially designed for filling orders as they come in. It is claimed for the Westinghouse system that it shows in the lamps 70 per cent. of the power given to the driving belts by the engine—a very good return for converters and alternating dynamos. Altogether Professor Forbes's paper is interesting and fairly instructive, notwithstanding the reserve with which the author treats the question of capital and working expenses in connection with central-station lighting, and his evident disinclination to recommend the Westinghouse system for England.

Among the papers contributed to the Mechanical Science Section of the British Association, was one by Mr. R. Percy Sellon upon the use of the electric light in the night navigation of the Suez Canal, which we refer to here in order to show that we are always prepared to recognize what there is good and useful in any description of electric lighting. Experience has abundantly proved that electric lamps for ship use, and for a variety of marine purposes, are as conspicuously in their place as they are out of it in the case of ordinary street lighting, and for other applications over which speculators persist in wasting money which, in general, does not belong to them. An example in point is supplied by the history of the opening up of the Suez Canal for night transit, which has practically increased the carrying capacity of the Canal by 50 per cent.—although it would not be correct to ascribe all the credit for this to the electric lamps borne by the ships, seeing that the Canal Company have co-operated in the matter by putting down a number of light buoys in the Bitter Lakes, and erecting guiding lights along the banks, supplied with gas from extensive works at Ismailia. The saving of time passing through the Canal for steamers carrying electric lights for night navigation is about 24 hours, which is worth £70 to £80 to first-class passenger steamers.

After a long period of quiescence, during which it may be supposed that plans have been perfected and negotiations completed, there is again a sound of the proposed electric lighting scheme for Birmingham which Messrs. Chamberlain and Hookham took in hand some months ago. According to a statement appearing in a local newspaper, the promoters are at last quite ready to make their formal applications to the Board of Trade and the Corporation, and are sanguine of success in a commercial sense. It is further stated that the supply of electricity is to be by meter at the rate of 8d. per unit; which is equivalent to gas at 6s. 8d. per 1000 cubic feet. At this rate, the average cost of an 18-candle power incandescent lamp would be a little under $\frac{1}{4}$ d. per hour, and of an ordinary arc lamp 4d. per hour. There is to be no restriction as to wiring houses, which consumers will be graciously permitted to get done (at their own expense) by any electrical fitting firm they may select; or the Company will undertake the work if desired. The average cost of the internal wiring is estimated at about £1 per lamp, plus an initial charge of £2 10s., which appears to be contemplated as a sort of entrance fee. The necessary electroliers and glass shades are estimated to cost 7s. 6d. each, and the lamps, which are to be charged for at 4s. each and are estimated to last 1200 hours, are also to be provided by the consumer. Thus it is evident that Messrs. Chamberlain and Hookham's customers will have a good deal to pay, in one way or another, for the blessings of electric lighting, if they ever rejoice in them. It is to be noticed that—probably by way of compliment to the Corporation gas—the normal incandescent lamps are estimated to afford an average illuminating power of 18 candles, instead of the 16-candle power usually assigned to these lamps in places where the gas is not quite so brilliant. Taking this statement of the contemplated rates of charge for electric lighting in Birmingham as authoritative, however, can any reasonable man require further information as to the causes why the system has not become more popular in this country? We would direct Professor Forbes's attention to this point. Here is a case of one of the chief towns of the Kingdom, which is at the present moment nearly, if not quite, destitute of the blessing of electric light. Is this due to the Electric Lighting Act, or to some other cause? It is proposed to supply the deficiency, however; and the first fact that stares one in the face from this project is that the electric light is to cost at least three times as much as gas in the town. In addition to this, the consumer is to do everything, and is expected to commit himself to heavy outlay for fittings, in spite of the consideration that of all the town electric lighting schemes that have been started in different parts of the country during the past five or six years, those still in operation may almost be counted upon the fingers of one hand. It is worse than useless for electricians and their unreasoning friends to hurl abuse at the Electric Lighting Act until they are prepared to explain considerations such as the above, which are more significant with respect to the real position of electric lighting in this country than all the glozing lectures and papers that were ever written to bolster up the new system of lighting.

THE PETROLEUM TRADE.—Captain J. J. Vandergrift, President of the United Oil and Gas Trust, in an interview with a reporter of the *Pittsburg Commercial Gazette*, furnished some highly interesting information as to the condition of the oil trade in Western Pennsylvania and also the future of the Ohio petroleum trade. He claims that by next year there will not be enough oil produced in this State to supply the demand of consumers; and for this reason the world will have to go elsewhere to obtain its full supply.

NEW GASHOLDER PATENTS.

FROM information that has reached us from various quarters, we are able to state that several applications have been and are to be made to the Patent Office for devices for guiding gasholders without lofty guide-framing; so that in a short time gasholder builders who may be inclined to make a speciality of economical construction upon this principle will have a considerable range of choice of methods. This is a matter that illustrates, in a very striking way, the force of example, and it may also be read as a lesson upon the canon of patent law which forbids the patenting of a principle. The idea of dispensing with what we have called superior guide-framing for gasholders is so clear that it strikes one as almost amounting to an invention of itself; but when properly considered, this idea will be found, upon inquiry, to be only properly definable as a discovery. Thus it enables us to show the essential difference between a discovery and an invention; seeing that the establishment of the principle that lofty guide-framing is not necessary for gasholders is a discovery, while the devising of the means whereby this principle can be carried into effect is invention. This consideration leads on to another reflection, upon the question which so grievously afflicts inventors—the respective rights and claims of the original inventor and the later improver. This is a matter that interests the world at large, which is often more indebted to the improver than to the first inventor; but it is something upon which opinions and interests are, and will always remain, hopelessly divided. Yet it is possible to do justice between the first inventor and the crowd of improvers whom he is apt to stigmatize indiscriminately as copyists and infringers, by keeping in view the distinguishing qualities of a discovery and an invention. It frequently occurs that the two ideas are confounded in one example; so that it is difficult to say off-hand which is discovery and which invention—which is the principle, and which the application of it. Such confusion commonly happens when the publication of an invention is the first intimation to the majority of the community that a new discovery has been made in the arts. Take, for example, the matter of incandescent electric lamps. Here was a case in which the discovery that fine filaments or wires of carbon (rendered vividly incandescent by the internal friction of a strong current of electricity, and preserved from combustion by being enclosed in a vacuum glass) could be made use of for lighting purposes, was almost inextricably mixed up with the invention of means whereby such lamps could be made. The man who first described these lamps and gave them the form and general character which they afterwards retained, but which were previously unknown, naturally regards himself as the rightful owner of the whole thing—discovery as well as invention; and he can hardly be brought to see that the man who comes after him, and merely improves upon the manner in which his discovery can be carried into effect, has any rights at all. Take, again, the case of the discovery of the effect of heating air and gas upon their luminosity attending the combination in combustion. It is not many years ago that the idea that any good whatever could be effected by such means was generally scouted. A British Association Committee reported that heating air and gas up to the melting point of the materials composing the burners with which they experimented, had no appreciable effect upon the illuminating power of the flame. Yet, at the time when this authoritative declaration was published, the beginnings of the modern regenerative lamp were actually in course of development. We all know to what a pitch this development has been brought by the successive improvements upon the original embodiments of the discovery. In these two cases, however—of the incandescent electric-lamp and the regenerative gas-lamp—it is possible to say that the original inventor of the means was also the discoverer of the principle; or if he was not strictly entitled to this distinction, that at least was to him due the bringing into prominence and favour of the idea carried out in his invention. It is not so in the case of the attempts now being made to dispense with superior gasholder-framing. Mr. W. Gadd, in the specification which we published last week, is perhaps the first patentee in the field. But he does not lay claim to any credit for the general idea to carry out which his invention is designed; and he will not, therefore, be aggrieved if a score of other patentees with similar objects to his own, but holding different views as to the most hopeful way of securing them, should besiege the Patent Office during the next few months. We have reason to believe that some inventors have now plucked up heart for patenting notions of this kind that they have cherished more or less hopefully for years; while more than one perfectly futile scheme will see the light that has been talked over and dismissed as impracticable by half-a-hundred engineers. In brief, the abolition of gasholder guide-framing is a question of the day that will not escape in some of its developments the reproach of being a "fad" of the hour.

It is in connection with this subject that we desire to utter a word of warning. We believe thoroughly, for reasons that need not be repeated, that with due precautions a gasholder can be guided from the base; but we are not yet prepared to state what these precautions are to be. It is necessary to remark that nobody has yet demonstrated to general satisfaction what is the amount of stress that would be thrown upon the bottom rollers of a holder, supposing that there was nothing else to keep the holder stable. To take Mr. Gadd's case first, as being most immediate, and to frame the inquiry in its simplest terms, we pose the following question: A single-lift gasholder is 100 feet in diameter, and 24 feet high, and weighs 66 tons—What is the strain upon the bottom

rollers according to Mr. Gadd's plan? So far as we can see, there do not exist the elements required to furnish the solution to this question. This opinion may be wrong; but we should like to see the problem worked out. Or again, as the solution which we look for as of the first importance does not depend upon the acceptability of Mr. Gadd's device, let it be sought for on the lines of the Rotherhithe experiment: If it is not necessary to carry up external guide-framing to the full height of the holder, in order to ensure its stability, how high should it go? And what will be the method for determining the stresses passing through the rollers that are retained? No attempt has been made to deal with such questions as these; but answers should be found for them if the new departure in gasholder design is to be credited with other than an empirical character. It may be possible to erect gasholders up to say 80 feet diameter, with a system of guiding utterly wrong in principle, but made serviceable by a lavish use of material. It is when holders become large that the question of combining efficiency with economy in construction grows pressing, and any deviation from true principle becomes dangerous as well as costly. After regarding the subject from all sides, therefore, and having regard to the magnitude of the interests involved, we repeat the desire already expressed in these columns for something like a crucial experiment in connection with a gasholder required to be demolished, the conditions of stability of which could be ascertained at a comparatively small expense. It is impossible to lay down in advance the conditions under which such an experiment should be conducted; but any gas engineer in a position to initiate such an investigation would deserve the thanks of his fellows by setting himself to solve one or two questions of gasholder stability in a practical fashion. As one of our correspondents has pointed out, however, experiments are apt to mislead, unless intelligently conceived and properly interpreted. It would therefore be a study to propound the conditions of an acceptable experiment. In the meanwhile, we desire to impress upon all inventors of means for dispensing with gasholder framing, the potent fact that they have not yet made good their ground, lest they should be carried away by the prevailing fashion, and, with a bound over all intervening obstacles, regard that system of construction as easy which only a short time since would have been dismissed as impossible.

It may be interesting to state that the Rotherhithe gasholder has continued in regular work ever since it was first inflated with the additional lift. The guide-framing is considered to be actually stronger than it would have been if it had been raised to the full height, because it is composed of cast-iron columns; and there is a limit to the height to which a framing of this kind can be usefully carried. A cantilever may be disguised as a column up to a certain point; but beyond that the deception becomes impossible. This consideration is of the kind which we had in view when we stated that small holders could be constructed after erroneous principles which would not hold good with larger examples. Columns may be used in the old-fashioned way for holders up to what a few years ago would have been regarded as a large size—that is, up to double-lift holders of 200 feet diameter. To depend upon cast-iron columns for holders of three or four lifts in height, and exceeding 200 feet diameter, would evidently be to spend a great deal of money upon a method of construction which, even if it could be made passably secure, would illustrate the devotion of the maximum of material to the minimum of strength.

FINDING WATER BY DIVINATION.

THE subject of this article is of a class that rarely finds admission into the necessarily severe columns of a technical journal; and that we should propose to devote any of our space to a discussion of it is an example of the truism that "extremes meet." For whatever may be said about engineering in general, by critics occupying all the range from the position just filled by Sir Frederick Bramwell to that taken up by Mr. Ruskin—that is to say, from a perfunctory admirer who can see no evil in the Engineer, to the scorner who does not find anything good in him—it cannot be remarked with truth that civil engineering is a mystic craft, or that it demands occult powers in its practitioners. Yet there is a point, which it is our present purpose to exhibit, at which the matter-of-fact practice of the civil engineer comes into contact with something as utterly inexplicable as any of the mysterious powers professed by the ancient Magi, or narrated in Rider Haggard's most thrilling romance. We mean the use of the so-called "divining rod" for finding underground springs or streams of water. It is possible that some of our readers, having reached thus far, may be disposed to turn from this article in disgust at the mere idea of our proposing to discuss seriously such a piece of "downright humbug," as the use of this method of discovering springs of water has been called in our hearing, by men who have never seen it. It is possible, however, for a witness to testify faithfully respecting something which he has seen, even though he cannot explain it. Scientific research would lose all its charm if there were no mysteries to be first noted and then cleared up; and a fact which appears altogether unaccountable when first seen by itself, may in due course fall into its proper place in a chain of phenomena completed at a later time by the discovery of a last link which makes harmony and reason out of what was previously a bewildering jumble of disconnected observations. This argument is all very good, it may be objected, so long as it applies to facts; but it is open to a critic to contend that we have not yet made good the first premises, and shown that the divining rod is a fact and not a means whereby wide-awake charlatans occasionally succeed in deluding the credulous. It will therefore be as well to mention that in

what we shall have to state in the following account of the divining rod, we explain nothing and guarantee nothing beyond the plain narration of what was witnessed by a party of visitors to Lisburn on the occasion of the recent meeting of the North of Ireland Gas Managers' Association in that prosaic town.

It will be more convenient, however, to recount by way of preface what is generally reported of the nature and use of the divining rod for finding water. Sufficient information for the purpose may be found collected in two articles which appeared in *Chambers's Journal* for Feb. 18 and July 21 of the current year. The first quotes an account of a remarkable experiment in Suffolk, published in the *East Anglian Daily Times*, conducted by a Mr. Lawrence, from Bristol, with the object—which appears to have been obtained—of determining the best site for a public well for the village of Wattisham. The account runs as follows:—

The articles used for the purpose of indicating the presence of water underground were a piece of steel spring about a foot in length, and a v-shaped hazel stick. The yard behind Wattisham Hall was first selected for the trials. With the piece of spring held in a bowed shape in front of him, and firmly grasped with both hands, the operator slowly stepped about the yard. In a very short time, and at one particular spot not far from the house, the spring began to twist and curve about in the most uncontrollable manner. With the hazel stick tightly held apex downwards, he again stepped towards the same spot, when the upward movements and twists of the stick were so violent as to break it. Mr. Lawrence predicted that at this spot a plentiful supply of water would be found.*

This description of the method of divination is corroborated by the writer in *Chambers's Journal*, by reference to another experiment witnessed by him near Bath, with the exception that in this case only the hazel rod was used. The statement continues: "It is certainly most interesting to observe the sudden and apparently uncontrollable movement of the wand, as held by the diviner, in certain spots, whilst it remains perfectly inert in others, and again, perhaps, moves very slightly. . . . In the case indicated . . . water was found." This account sufficiently describes the divining rod itself, and the method of using it; while, of course, it leaves the explanation of its action wholly in the dark. The appearance of this article attracted other communications upon the same subject which, as already stated, were published five months later. One of these names John Mullens* and Lawrence as the chief "diviners by the rod" of the age—how queer this sounds!—and claims virtual infallibility for the first, who is described as "a working mason on a gentleman's estate, and an unpretending honest man, who, if desired, sinks and builds his own wells and charges nothing if the water is not found." Mullens convinced the Vicar of the parish—naturally, an incredulous person—by tracing out the running sewer from the vicarage house for a long distance through the garden; not a hint of it being discernible above ground, and its position being known only to the Vicar himself. "He discovered our water-mains and branches here, wherever he crossed them in the course of his journeys, greatly to the surprise of an engineer from Sheffield who constructed our reservoirs." Another correspondent describes the use of the rod, consisting of "a small branch of white-thorn about 18 inches long in the shape of the letter Y. When the man—who was a mason—tried to find water, he walked slowly over the ground clasping the rod firmly with both hands near to the forked branches; and when the branches moved upwards, he said there was a spring of water below, and gave his opinion as to the depth of it from the surface. I was sceptical about the rod, and thought he moved it by some sleight-of-hand; but in the course of the day I was convinced it was not so." There is more to the same effect; but enough has been cited to show that practitioners with the rod have in different places convinced capable, and, in the beginning, sceptical observers, of their trustworthiness.

Now for our own piece of evidence. At Lisburn, upon the occasion of the meeting of the North of Ireland Association of Gas Managers, we met Mr. John Stears, of Hull, who claimed to be peculiarly gifted with the power, whatever it may be, of discovering not only water but also iron underground, by virtue of the rod. It was about eleven o'clock in the morning, when Mr. Stears volunteered to exhibit his remarkable powers—first privately, and

afterwards to a number of gas managers attending the meeting. A forked hawthorn twig, about 14 inches long, and V-shaped, was cut from a hedge and roughly trimmed of its leaves. Mr. Stears, holding a limb of the fork in each hand, with the apex to the front, slightly inclined downward from the horizontal, walked at an ordinary pace across the roadway. Very soon after quitting the curb the twig bent violently in his hands, which were quite rigid, "Here is the gas-main," he remarked. The revelation was so startling that other tests were demanded, which the operator continued to give for a space of nearly an hour in different parts of the roadway before an interested crowd of witnesses, many evidently "convinced against their will." Mr. Stears found in this way gas and water mains, underground drains, and springs; the indications in the cases of the two kinds of mains being substantiated by reference to competent authorities. It should be stated that Mr. Stears was comparatively a stranger in the town, and that the movements of the twig, however caused, were not such as he could have made by his own hands, which were, moreover, held several times by sceptical witnesses, who could neither stop the agitation of the twig nor detect any movement in the muscles of the operator. A hooked fish does not cause springing of the tip of a fishing-rod more apparently independently of the volition of the fisherman, than did this mysterious influence, whatever it was, of the end of the twig held firmly by Mr. Stears. The same action was afterwards repeated with a piece of soft copper wire. The movement of the twig was so curious, however, that one of the witnesses carried it off for examination, but without result. Without attempting to explain anything, therefore, we are able to declare, on the faith of many more eye-witnesses than would be required to hang a man, that on this particular morning in Lisburn Mr. John Stears did hold in his hands a freshly-cut twig, which did show very remarkable jerkings and bendings up and down. So much is positive. Then it was stated upon competent authority that gas and water mains underlay the roadways at the points where these manifestations occurred. Not one of many interested and incredulous spectators who were allowed to approach and watch the operator, and even to hold his hands, could detect any movement upon his part which would account for the movement of the twig; and nothing of the sort could be discovered by any of the tests which, upon the spur of the moment, were applied for this purpose. Further than this our testimony does not go. It is only fair to Mr. Stears, however, to state that he has since expressed perfect willingness to prove his powers in this line to anyone, and to submit to any reasonable test conditions. He does not profess to explain his powers in any way. He says that he discovered his own possession of it accidentally, and has for some years tried to find it in other people with whom he has been brought into contact. Some—a very small percentage—have something of the power, but he has never met with anybody who possesses it in as high a degree as himself, seeing that he can find both water and iron.

Mr. Stears informs us that while in Lisburn he traced all the drains and pipes [at a school, and was informed by the superintendent that he was correct in every case. He has also, as he states, found a spring in a gas-works, which was used to fill the gasholder tanks. The tank was sunk in a rather dry site, so that although there was a little drainage water, the sump-hole pump could not be kept in regular work. Water being urgently required, the divining rod was called into requisition; and the well-sinker was instructed to go to work at a spot indicated, although he protested that it would be useless. However, at a depth of 15 feet water was found; and when the well was deepened to 21 ft. 6 in. a spring was tapped which kept the pump supplied day and night until the tank was filled. Mr. Stears has furnished us with full details of the operation, and a plan of the site.

This is the whole of the story, of which our readers may make what they please. We only vouch for so much as we have seen. If there is trickery in the practice, it should be discoverable; if not, it is a truly remarkable phenomenon, which we are not bound to reject because we cannot account for it by any reference to known laws of Nature. The more experience man gains, the less hasty is he in recording opinions respecting matters which cannot be understood. Anybody who will take this subject in hand, however, and investigate and report upon it in a scientific spirit, will confer a benefit upon science. It is unendurable that amid all our colleges and technical institutes and high schools, men should go at large professing occult powers with reference to such a common matter as that of the discovery of underground springs and water-courses, and should deceive the public, if there is deception in the practice. If, on the other hand, it is a true power of Nature—which it is extremely hard to believe—why, let it be recognized as such, and let it receive its due acknowledgment.

* Since this article was in type, the following paragraph has appeared in several of the London newspapers:—An extraordinary series of experiments have been conducted on the site of the Hastings new workhouse. A point which has been warmly disputed in connection with the ground has been as to whether or not water was to be found there. It was at last decided to employ a "diviner," named Mullins, to test, by the phenomenon of a divining-rod, the capacity of the site in the matter of water supply. Mullins sent exceptional testimonials; having found abundance of water by divining for Lord Winchelsea, Lord Stanhope of Sevenoaks, Lord Lee, the Earl of Dysart, the Bradford-on-Avon Corporation, &c. From the fear of drawing together an inconveniently large crowd upon the grounds, the experiments were kept very private; but the matter became known to the local press representatives, of whom several were present, in addition to the Chairman of the Board (Mr. Winter, J.P.), the Building Committee, and the Board officials. Mr. Mullins was apparently highly successful. His plan was to walk with a hazel-twig suspended between the fingers; and when nearing certain points in the ground, the twig would become agitated, and twist right round in the "diviner's" hand. In order to prevent imposition, several sceptical persons held the ends of the twig very tightly in their hands whilst Mr. Mullins was experimenting; but even then it moved as usual, and in some instances snapped asunder in evading the attempts at resistance. According to the "diviner," there is an ample supply of water; and he calculates that at the highest points of the field there will be no necessity to dig more than 60 or 80 feet, whilst at some other points it might be found at 30 or 40 feet. The Committee of Guardians expressed themselves highly satisfied with the present stage of the experiments; but the well-sinking trials will be awaited with great interest.

THE Burlington (Iowa) City Council have decided that hereafter plumbers and gas-fitters, and all others whose calling obliges them to open the public streets for the purpose of tapping any gas or water main, sewer, drain, &c., shall take out a licence, to last one year, and to cost the recipient \$25. Having received the licence, the holder, prior to opening any street for the purpose of making a pipe, drain, or sewer connection, is required to furnish a bond, the sum of which is to be determined by the nature of the situation and surroundings, in regard to the possible amount of damage that might be caused by any neglect on the part of the contractor or licensee. A permit for each opening has to be obtained, the fee for which is to be \$1. The ordinance contains many other provisions, some of which are of a very stringent character.

Notes.

THE PRODUCTION OF CREOSOTE FROM PINE WOOD.

The extension of railroads to the Southern States of America having created a large demand for creosote for the preservation of timber, works have been established especially for its production from pine wood; and in a recent number of *Invention*, some particulars were given of the process employed. It differs from the ordinary method of charcoal burning, inasmuch as air is entirely excluded, external heat is applied, and a larger quantity of oily products are obtained, which in the ordinary way are lost in supporting combustion. The first condensable products are water and acetic and other acids; afterwards alcohol and phenoloid bodies; and, lastly, the heavy hydrocarbons used in creosoting. Gases are evolved in the following order:—Carbon dioxide, carbon monoxide, methane, ethane, ethine, and (at high temperature) hydrogen, due to the decomposition of hydrocarbons. The retorts are made of cast or wrought iron or steel; the two latter materials being especially used for large retorts, and the former preferably for small ones. They are generally made cylindrical, between 3 and 7 feet in diameter, and from 5 to 30 feet or more in length. The furnace gases are passed under a protecting brick arch below the retort (which is consequently first heated by radiation), and are then brought back over the retort. The most resinous pines, preferably those with a deep-red section, are chosen for giving the largest yield of oily products; the old trees which have been previously tapped for turpentine being especially prolific. The fuel for carrying on the process is the gas from the distillation as soon as it will burn, either direct or preferably drawn through scrubbers, and, if necessary, stored in a gasholder, although at the commencement wood or charcoal is used. The temperature for the first 12 hours is kept at about 290° C., afterwards gradually increasing, and finishing off at about 450° C.; there being left behind a poor charcoal, having the following percentage composition:—Moisture, 3·41; ash, 0·54; carbon, 63·80; volatile matter, 32·24. The following figures are the averages of 16 charges, and represent the yields in ordinary working:—Weight of wood, 4573 lbs.; light oil, '875 to '950 sp. gr., 13·8 galls.; pine oil, '950 to 1·040 sp. gr., 73·5 galls.; pyroligneous acid, 1·020 sp. gr., 185 galls.; charcoal, 1511 lbs. The distillates are allowed to settle, when the oil floats on the acid. It has a specific gravity from '97 to 1·03, retains a little acid, and contains also some volatile oil. The flashing point is 50° C. Its main application is for creosoting; and for this it is partly fractionated till the lighter and deleterious bodies, amounting to about 15 to 20 per cent. of the whole, are removed.

ELECTRO-CALORIMETRY.

At the recent meeting of the British Association at Bath, Messrs. W. Stroud and W. W. Haldane presented a paper on the above subject, in which they stated that further experiments had been made with the electrical method of measuring the specific heats of liquids described at the meeting of the Association at Manchester last year. The apparatus they have now adopted consists of two calorimeters—cylindrical vessels composed of thin hard-rolled sheet brass. In each vessel is a resistance coil of insulated platinum wire, fitted by means of a screw-plug of ebonite. One calorimeter, called the standard (the left-hand one), contains a thermometer; whilst the other is the working vessel, provided with a screw-plug for the admission of a pipette, used in changing the quantity of liquid. Connecting the two vessels is a thermopile, made of iron and German-silver wire. All the fittings are by screws, with leather washers, or by india-rubber tubing; so that leakage and evaporation are entirely avoided. Instead of the complicated methods formerly adopted for agitating the contents of the calorimeters, the very simple and exceedingly effective one of shaking the vessels themselves has been employed. For this purpose the calorimeters are enclosed within a suitable box, so as to be easily rocked or shaken. The authors discussed fully the ways of adjusting the rates of rise of temperature when electrically heated, so that these rates might be made as nearly as possible equal. This may be effected by shunting one of the coils, or by adjusting the amount of liquids in the calorimeters; the latter method being found to be the best. For the elimination of small errors, methods analogous to those adopted in accurate weighing may be employed.

REAPPEARANCE OF OLD GAS-MAKING PROCESSES.

The tendency displayed by the natural gas companies of Western Pennsylvania and the Ohio Valley to raise their rates for gas supplied to manufacturers, has caused attention to be directed to oil-gas processes, a great variety of which are now seeking public favour. A recent issue of the *American Manufacturer* contains descriptions of two so-called new processes of this order. One of these is being introduced by the Naysmith Fuel Gas Company, of Pittsburgh. It comprises a system of iron retorts, set after the fashion of ordinary coal-gas retorts. Two horizontal tiers of these retorts, each having over it in the arch a cast-iron superheater in shape like a V-pipe, constitute a bench. One superheater is for steam, and the other for air, which are brought to the front of the bench, and there admitted into one leg of the superheating pipe, passing through it to the other leg, where the currents of hot air and steam each encounter a small stream of crude petroleum. Thus carburetted, the vapours pass through the retorts, which are maintained at a temperature of about 900° Fahr., where the gas is fixed. From a condensation-box attached to the last retorts, the gas is led straight to the holder. A portion of the gas is used as fuel for

heating the retorts and raising steam. The process is reported to make gas at half the cost of natural gas, using Lima crude oil as the raw material; but the particulars published are very meagre. The other system is that owned by the Brooks Gas Process Company. In this case the bench contains six sets of retorts; each "set" consisting (as well as may be understood from an exceedingly poor description) of four horizontal branches subject to the heat of the furnace. A boiler supplies steam for conversion into gas, and to drive an air-blower. There is also a cooler for condensing the gas before it passes into the holder; but there are no washers or purifiers. Crude petroleum is pumped into overhead tanks, and thence flows through pipes into the front end of the retorts. Here it meets with steam; and the oil and steam become mechanically mixed. "It then passes into the next section; and meets the disintegrators, where chemical action begins to take place, and is forced through one disintegrator after another, with constant impinging against the inside of the retorts, until it has passed through all the disintegrators and sections into the regenerative chamber, where the chemical union becomes complete, and is then fixed or non-condensable gas. It now passes, with the right manipulation, through coolers into the holder, and is ready to be sent through the mains a 24-candle power gas of exceeding brilliancy." Mixed with tenfold its bulk of air, this gas is stated to resemble natural gas. From all this it will be seen that old processes under new names are being tried once more, with a view to compete with natural gas.

WAVERLEY ASSOCIATION OF GAS MANAGERS.—The fifty-fifth half-yearly meeting of this Association was held in the Tower Hotel, Hawick, on Thursday, the 13th inst.—Mr. J. Smith, Manager of the Hawick Gas-Works, presiding. There was a fair attendance of members. The Secretary (Mr. G. Taylor) read the minutes of the previous meeting, which were approved of, and showed that the funds were in a healthy condition. After a short address by the Chairman, in the course of which he mentioned that, through the use of gas cooking-stoves, the consumption of gas in Hawick during the summer had been increased by about 3 million cubic feet, various subjects connected with the manufacture and use of gas were discussed. Mr. Taylor was then presented by the Chairman, in the name of the Association, with a valuable gold medal, of artistic design, for his past services as Secretary to the Association. The medal was in the form of a wet gas-meter. A shield on one side bore the following inscription:—"Presented to George Taylor, Esq., by the Waverley Association of Gas Managers, as a mark of esteem for his services, 1888;" and on the other side was a shield bearing a monogram formed of the letters "G. T.," encircled by the name of the Association. After the business, the members, joined by a number of friends, dined together; the positions of Chairman and Croupier being ably filled by Mr. Smith, of Hawick, and Mr. W. Robson, of Selkirk. During the day the members of the Association visited the Hawick Gas-Works, under the guidance of Mr. Smith, and congratulated him on their very efficient condition. It was arranged to meet at Portobello in April, and at Melrose in September next.

THE HALIFAX GAS SCANDAL.—Our correspondent at Halifax (writing yesterday) says: "The position of affairs at Halifax in respect to the so-called gas scandal is almost unaltered from last week. The only item worth mentioning is that both parties—that is, the Mayor and Town Clerk, on one side, and Mr. T. K. Fox and his Solicitor, on the other—are agreed upon the terms of the indemnity; and the document now only awaits signature. It was expected that the Mayor would have appended his signature on Thursday, as an interview took place on that day between Mr. Rhodes (Mr. Fox's Solicitor) and the Mayor and Town Clerk; but, after a consultation, it was decided to defer the signing until the monthly meeting of the Town Council to be held on Wednesday of next week. It is to all appearance thoroughly understood by the members of the Town Council that the matter shall be proceeded with, and the allegations sifted to the bottom. Alderman Riley, the Chairman of the Gas Committee, declares that he knows nothing of any malpractices or irregularities, and strongly disapproves of the manner in which the subject was discussed by the Council in public during his absence from home. On the other hand, the general feeling among the ratepayers is something like this: The Mayor having publicly stated at the Council meeting that three persons would be implicated in the allegations to be made when the indemnity is signed, they ask, Why should Mr. Carr—who has carried out his duties as Gas Manager with signal ability—be singled out to bear the brunt of the battle, and the other two escape? The Mayor's answer to this is that Mr. Carr alone amongst the three is a servant of the Corporation; and they could compel him only to take proceedings after the indemnity was signed. The course taken with respect to Mr. Carr has undoubtedly strengthened the determination of the ratepayers, and of a great portion of the Town Council, that the indemnity shall be given, and the allegations (whatever they are) stated in open Council meeting, and thereby given to the public. I hear, however, on good authority, that the Mayor is inclined to the course of signing the indemnity forthwith. He is just now at Scarborough; but, as he is known to have had a long interview with Mr. Fox and Mr. Ellis Lever, when a large number of documents were brought under his notice, and certain information of a private nature given to him, he may, acting upon such information as he possesses, decide to precipitate matters, and bring the subject to a crisis in time for the Council meeting. Mr. Carr terminates his engagement with the Corporation at the end of the present week."

Communicated Articles.

THE GUIDE-FRAMING OF GASHOLDERS.

[The introductory lines to the letter by "Theory and Practice" in the JOURNAL for Aug. 21 would probably have recalled our readers' minds to the series of articles on the above subject commenced in our pages towards the close of last year, and the publication of which has been unavoidably interrupted. We are now, however, in a position to complete the articles; and we give to-day the notes to the third of the series, which appeared on the 31st of January last, together with the corrections of a few errors which have inadvertently crept in, reserving for an early issue the concluding instalment of this interesting communication.—Ed. J. G. L.]

NOTE I.

Iron shortens or lengthens about $\frac{1}{12000}$ th part of its length, for every ton per square inch strain upon it. This property of the elasticity of iron is very apparent in a large gasholder. For example, we will take the shortening of the top curb of a gasholder 200 feet diameter. The circumference in inches would be 7540, one-twelve-thousandth of which is 0.628 of an inch. Therefore the curb would shorten 0.628 of an inch for every ton strain; and as top curbs are frequently strained up to 4 tons per square inch (sometimes a very great deal more), the total shortening would be at least $2\frac{1}{2}$ inches, which means a reduction in the diameter of more than $\frac{1}{4}$ inch. It follows, therefore, that the top rollers are off the guide face by $\frac{1}{4}$ inch all round, when the holder is right up, and the curb is fully strained. The strain on the top curb is, of course, due to the pull of the top sheets; and this varies according to the pressure of gas within. When the holder is "down," there is practically no strain on the curb; and it is therefore at its full diameter. The roller carriages may be adjusted so that the rollers are absolutely tight against the guides when in this position; but immediately the holder rises, the pull of the sheeting compresses the ring, and so draws off the top rollers—making "play"—and each time the holder picks up weight (that is, cups), the curb shortens and the rollers leave the guides still more. This cannot be allowed for by adjusting the rollers when the holder is at its full height, because when the holder descends and the curb swells in diameter, the strains on the rollers would be enormous, besides over straining the framing.

Of course, this property of shortening under compression and lengthening under tension is applicable to the whole structure; the above has been chosen merely as an illustration. Therefore we see at once that there is no such thing as absolute and perfect fit in a huge structure like a gasholder; and, consequently, it would be very unwise to construct holders with only a few feet of guide-framing, as they depend upon perfect fit and absolute rigidity in all their parts. It is this same principle that makes it necessary to have the lifts of the gasholder at least one-fifth of the diameter in depth, to prevent tilting, and to economize material.

Again, the difference in temperature between winter and summer will cause the lengths of the various parts to vary. They may be $\frac{1}{10000}$ th part of their length shorter in winter than in summer.* These variations, due to elasticity and temperature, modify to a certain extent the cantilever treatment of the guide-framing, because of the impossibility of getting each part to perfectly do the duty and fill the office expected of it.

NOTE J.

The pressure of the bottom rollers against the tank guides varies according to the height of the guide-framing. If the guide-framing be carried to the full height, the pressure of the gasholder against it is shown in fig. 28; the wind being uniformly distributed throughout the whole height of the holder, and acting in a horizontal direction. The pressure is distributed amongst the rollers on the three lifts approximately as shown. We say approximately because, should the rollers on the middle lift be too weak, or yield a little to the strain, it would throw more pressure on the rollers above and below. If the guide-framing be carried to the height of two lifts only, the pressure may be taken as in fig. 29. If the framing stop short at the outer lift, the pressures are indicated in fig. 30.

In all cases D represents the diameter of the holder; and d the depth of one lift—both in feet. The pressure is the resultant pressure in pounds distributed on the one circle—not the pressure on each roller. The arrows indicate the direction. The pressures given are those due to the wind only. The effect due to the weight of snow, can easily be added, if desired.

It has been suggested that the gasholder has a tendency to fall

against the wind, because its centre of gravity is above the centre of pressure of the wind. This can never happen as long as the base is restricted from advancing. It is impossible to cause the heavy headed stick shown in fig. 31 to fall backwards when struck in the direction indicated by the arrow P, although its centre

of gravity is above the point struck. It is bound to fall forwards, owing to the restricted base. A gasholder is an analogous case. When subject to a sudden gust of wind, it has a momentary tendency to fall backwards, or, more correctly, to thrust the bottom curb suddenly forward, hard against the guides. But as it meets with resistance, the top, of course, goes forward; and, if the wind is a steady, constant push, the pressures given out will be approximately as indicated in the foregoing diagrams.

NOTE K.

Even in the case of a simple plate girder, the exact calculation of the buckling tendency is practically impossible—the extent of stiffening necessary for the web has been determined by experience, and is quite foreign to all ordinary formulæ relating to the strength of girders, which formulæ only provide for the strength of flanges and web to resist the load, omitting the buckling tendency altogether. Speaking on this subject, Weyrauch states that "experiments have long shown that the plate-girder fails first by side buckling; the forces thus arising elude any systematic investigation."* If this be true for a simple plate-girder, how much more so for a complicated structure like a gasholder. In a single column or strut, subject to direct load, the determination of the buckling tendency is very difficult. How much more so, then, for a column built up of a group of columns, latticed together, and subjected to forces acting indirectly upon them and in various planes and directions. The formulæ given in the article, therefore, are to be preferred to a deep mathematical investigation based on merely theoretical conditions, and which is likely to be very much wider from the truth.

NOTE L.

The general formula for the strength of a cylindrical cantilever is $\frac{I C}{r L} = W$.

Where I = the moment of inertia of the section.
 C = the ultimate (tensile) resistance of the material per square inch (say, wrought iron, 20 tons; cast iron, 10 tons; and steel, 30 tons).
 r = radius (external).
 r_1 = radius (internal).
 L = length of cantilever.
 W = breaking weight in tons.

Or, filling in the value of I for a circle,

$$W = \frac{r^4 - r_1^4 \times .7854 C}{r \cdot L}$$

All other rules found in text-books are based upon this, though the way in which they are expressed may vary. Humber, Molesworth, and others, give rules which can be proved to agree with the above.

For very thin cylinders, however, it is not thought necessary to burden the formula with the two radii, as the difference is so slight Rankine, Clark, Fairbairn, Trautwine, and others therefore substitute the following approximation,

$$\frac{A D C}{4 L}, \text{ or } \frac{.7854 D^2 t C}{L}$$

Where A = the sectional area in square inches,
 D = the diameter of the cylinder,
 t = the thickness.

As regards the constant C , Fairbairn found, from several experiments, that it was about 13 tons per square inch for wrought iron (Trautwine gives 21 tons).

Experiments have been made with thin wrought-iron tubes, varying from 12 inches to 24 inches diameter, and from $\frac{1}{4}$ inch thick; and it was found that, as the thickness is reduced, the strength decreases at a greater ratio, and that the strength does not advance exactly as the diameter, but at a somewhat less ratio.

The general formula when applied to the experimental 24-inch diameter beam gives a breaking weight about double of that at which the tube actually broke; and the experiments go to prove that, as the diameter increases, the formula becomes more and more unreliable—the divergence accelerating rapidly; this being due to the fact that the formula does not provide for buckling or lateral stiffness. Mr. B. Baker, Mr. D. Kinnear Clark, and others, draw attention to this omission in the general formula.†

In the case of an iron ship, the skin is more than strong enough to take the direct strain upon it; but over and above this, it is stiffened by stays. According to Rankine, the space between the stays should not exceed (say) 40 times the thickness of the skin;

* See Barlow's "Strength of Materials," p. 280.

* See "Strength and Determination of the Dimensions of Structures of Iron and Steel," by Dr. J. J. Weyrauch; also Box, on "Strength of Materials," gives numerous examples proving this.

† See "Rules and Tables for Mechanical Engineers," p. 512.

otherwise the skin would yield by buckling.* The same applies to very hollow beams. They must be stiffened up, or they will yield by buckling; and for this the ordinary formula makes no provision. We, therefore, see its inapplicability to the gasholder for determining the strains. Something more is wanted to go hand in hand with it, and that is an allowance for buckling, distortion, or, as it is sometimes called, *wrinkling*, which allowance has been made in these articles.

NOTE M.

The columns on the lifting or tensile half of the cantilever are, of course, aided by their own weight, and the weight of the allied framing. The columns near the axis have very little lifting force upon them. Consequently their own weight more than balances it; but as the columns recede farther from the axis, the lifting strain increases until it exceeds the weight of the column. The actual upward lift on the outermost column is, of course, the difference between the calculated lift, and its own weight; assuming the structure to be a perfect cantilever. The columns on the crushing side of the cantilever guide-framing are, of course, further strained by the addition of their own weight. As the wind may blow from any quarter, all the columns must be of equal strength, as each in turn may be the most severely strained one.

The strength of a column is, of course, increased to a much greater extent by adding to the sectional area than it is impaired by the additional weight. Again, the heavier the structure, the greater is the dead weight to set in motion by the capsizing forces. It is to this, added to their individual transverse strength, that the columns in the old style of guide-framing mainly owe their stability.

ERRATA.

First Article (Vol. L.).

Page 792, Conclusion 4 read as follows:—*That a telescope gasholder is even worse, unless the guide-framing exceeds one-seventh of the diameter in height, owing to lever tower.*

Page 793, line 16 (first column), for "inner lifts" read "inner lift."

In the same column, line 57, for "moments round X" read "moments round O."

Page 793, line 44 (second column), for "the eight of the outer lift" read "the height of the outer lift."

Second Article (Vol. L.).

Page 963. In figs. 7 and 8 the arrows representing wind pressure are shown of equal length, they should vary in length; being greatest in the centre, and falling off on either side gradually.

Page 964, line 14 from bottom (second column), for " $= 14\frac{1}{2}$ tons" read "28,286 lbs., say $12\frac{1}{2}$ tons." The rule following to be altered thus: "Or approximately, three times the diameter, multiplied by the depth of one lift = the compression on the bottom curbs (in pounds) due to the racking effect of wind pressure, when the inner lift only is above the guide-framing in a treble-lift holder; leaving therefore in this case about 32 tons for snow effect."

Page 965, line 36 (first column), substitute, for "amounts to" the following:—"Is approximately 25 times the diameter, multiplied by the depth of one lift, in a three-lift holder with two lifts towering above the guide-framing, which, in this case, is $25 \times 200 \times 45 = 225,000$ lbs., or fully 100 tons."

Line 5 from bottom, substitute for "this" "which."

Third Article (Vol. LI.).

Page 189, fig. 23, substitute " $\frac{1}{2}$ d." for $\frac{1}{2}$ D. on the right-hand side.

Page 190, line 38 from the top of second column, for "movement" read "moment." In the formulae 23 lines from bottom for " d^2 " put " d_1^2 " in both cases. Page 191, line 29 from foot (first column), read "columns" for "column." Page 192, line 15 from foot (first column), for "fig. 25" read "fig. 26."

MODIFICATION OF HARCOURT'S COLOUR TEST.

By H. LEICESTER GREVILLE, F.I.C., &c.

Chemist to the Commercial Gas Company.

An article on this subject, by Mr. William G. Hicks, appeared in the JOURNAL for the 11th inst.; and as I have had some ten years' practical experience in the use of the Harcourt tests, and have myself introduced some modifications of the original apparatus, I should like to contribute a few remarks on the subject.

In the first place, I cannot see in what possible way the method of determining the various impurities in coal gas described by Mr. Hicks are modifications of, or, indeed, in any way connected with the Harcourt colour tests. The only connecting link, as far as I can judge, is the lamp for the determination of sulphur compounds. The term "colour test" speaks for itself, and is essentially a correct title for Mr. Harcourt's tests. Carbon disulphide, sulphuretted hydrogen, and carbonic acid are all determined by the use of colour standards, with the result of placing in the hands of comparatively unskilled people a method of testing which, although not strictly accurate, is sufficiently correct for guidance in practical gas purification, and is indeed for this purpose invaluable. Mr. Hicks does not propose to use these colour standards in his so-called modification of the tests; and his methods are simply those already well known to chemists. The determination of ammonia by means of passing a known quantity of gas through test acid, and subsequently titrating by test alkali, is that in daily use as the Referees' test; and the direct passage of the gas through a known quantity of test acid in a tube, using an aspirator to draw the gas through the liquid and measure, is a method I have employed as a rough test for many years past. It is only practically available where the proportion of ammonia in the gas is comparatively large. The estimation of carbonic acid by means of barium hydrate is a well-known method which has been frequently described. The process recommended for the estimation of sulphuretted hydrogen is open to very grave objection, owing to the well-known solubility of the gas in aqueous solutions. I gather

from Mr. Hicks's description, that the amount of sulphuretted hydrogen present in a certain volume of gas is inferred from the saturation of a known volume of an aqueous solution of lead acetate of definite strength, calculated on the basis of the known reaction between lead and sulphuretted hydrogen. Before, however, sulphuretted hydrogen passed through the solution so as to be indicated on the lead paper can be taken as a guide to the completion of the reaction, not only would the lead in the solution have to be converted into sulphide, but the water present would have to be charged with sulphuretted hydrogen, and the effect of this would be to considerably under-estimate the true amount of sulphuretted hydrogen present. The error from this source would also be a variable one with variations of temperature and pressure; the absorption of sulphuretted hydrogen by water increasing largely as the temperature decreases. The objection to the method of sulphuretted hydrogen determination recommended by Mr. Hicks applies with still greater force to his determination of carbon disulphide, as the volume of liquid employed would probably be as large, while the amount of sulphuretted hydrogen originally present would be smaller, and the percentage error would thus be proportionally increased.

With regard to temperature and pressure corrections in determinations of this character, I must confess to have, as a rule, ignored them, as the methods of operation are not, in my opinion, sufficiently correct to necessitate such refinement. Mr. Hicks, it is true, obtained as much as $6\frac{1}{2}$ inches of exhaust in his aspirator; but this could only have arisen from the employment of two tubes of solution, which is really unnecessary if the precautions are taken of pressing the capillary tube down to the bottom of the liquid, so as to divide the gas into minute bubbles, and of aspirating the current of gas at a sufficiently slow rate.

My own modifications of the Harcourt test were fully described in the JOURNAL for Oct. 12, 1886 (p. 652); but since the publication of the details, some useful improvements have been effected. The apparatus as now manufactured by Messrs. A. Wright and Co., of Westminster, is complete in a box, which can be carried about from place to place, and used as required. The box is so arranged that all the separate details of lamp, test-tubes, and measure aspirator are in their proper places. When in use, the front of the box slides out, exposing the apparatus, but at the same time protecting the lamp from draught; while a small hinge flap at the back allows the passage of light to the sight-box with its two tubes—viz., the colour standard, and that containing the lead solution. A test completed, the whole apparatus can be removed to another spot; and a fresh test taken without the delay of moving the apparatus piece by piece, and with the additional advantage of not requiring any special arrangements for shielding the lamp from draught or rain.

AN ARTESIAN BORING AT EALING.—Adjoining the new reservoir recently completed by the Grand Junction Water Company at Ealing, which was described in the JOURNAL for the 7th ult. (p. 241), artesian boring operations are being carried out by Messrs. Le Grand and Sutcliffe, and the chalk formation has just been struck at a depth of 321 feet from the surface. The base of the London clay was reached at 249 feet, below which came 72 feet of the Woolwich and Reading beds.

ELECTRIC LIGHTING IN BERLIN.—Experiments are now being made in Berlin with the electric light for street illumination; the first thoroughfare in which it has been introduced being the well-known avenue Unter den Linden. This is lighted by 108 arc lamps, suspended from chains running between cast-iron poles 24 feet in height. The latter are round, and ornamented with heads of lions and the Imperial arms at the base, and an eagle at the top. In the central avenue the distance between the lamps is about 100 feet; but in other parts, except at the crossing of the Friedrichstrasse, more. The motive power is supplied by four dynamos stationed in the adjacent Mauerstrasse; and the strength of each lamp is 2000-candle power.

THE MANUFACTURE OF COMPRESSED FUEL.—An addition to the various machines which have of late years been devised for converting into an article of commerce the dust or slack of coal, has just been made by the introduction of an appliance invented by Messrs. Mowll and Messenger, of Dover. The new machine is of comparatively small size; the briquettes made by it measuring only $4\frac{1}{2}$ inches long by $2\frac{1}{2}$ inches wide and $2\frac{1}{2}$ inches deep, and weighing $1\frac{1}{2}$ lbs. each. In making these briquettes, the coal dust is first mixed with 10 per cent. of crushed pitch; and the mixture is fed into a vertical mill, in which the ingredients are thoroughly incorporated by stirrers. At the bottom of the mill the ingredients encounter a jet of steam, which melts the pitch, and brings the mixture into a plastic condition. The mixture is then fed into a revolving mould; and the charge receives its initial pressure, from a horizontal plunger. The mould then makes a slight turn, and the partially compressed charge encounters another plunger, which gives it the final pressure. Another slight turn brings the compressed charge to an ejector, which pushes it out of the mould into a trough, from which the briquettes are removed by a boy on to a tray to be taken away for stacking. They are ready for use in about an hour from the time they have been delivered from the press. The action of the machine is continuous; and the rate of ordinary working is about 14 briquettes per minute, or five tons per day of 12 hours, which can be increased to six tons if necessary by working at a higher speed. The machine can be operated by unskilled labour, or be driven by horse or steam power.

* See Rankine on "Shipbuilding."

Technical Record.

SOUTH-WEST OF ENGLAND DISTRICT ASSOCIATION OF GAS MANAGERS.

HALF-YEARLY MEETING AT WESTON-SUPER-MARE.

The Twenty-second Half-Yearly Meeting of this Association was held on Tuesday, the 11th inst., at Weston-super-Mare. The PRESIDENT (Mr. H. Sainsbury, of Trowbridge) occupied the chair; and there were present a large number of members and friends.

The formal business, as reported in the JOURNAL last week, having been disposed of,

The PRESIDENT delivered a brief address, as follows:—

PRESIDENT'S ADDRESS.

Gentlemen,—It is to me a source of great satisfaction to find on the *agenda* paper of this meeting that “opening remarks” only are expected from the President, and not the formidable “inaugural address.” In looking over the proceedings of our past meetings, I was also pleased to observe that the remarks made by former occupants of this chair had been brief, and purely introductory to the business of the meeting.

It is a pleasure to all who take an interest in these Associations to hear of their increasing number and rapid growth of membership; showing as it does the willingness of our brethren to work no longer in isolation and self-sufficiency, but to carry out the great and divine law of “bearing one another’s burdens,” and impart to others the wisdom which has been bestowed upon us. In the JOURNAL OF GAS LIGHTING for Aug. 21 last, I notice there is a report of the first annual meeting of the North of Ireland Association of Gas Managers; and in the succeeding number a paragraph announcing the proposed formation of a similar Association for the Eastern Counties of England. We wish these new Associations, as well as those of older growth, much success and increasing usefulness. We have had the pleasure of admitting to our ranks a larger number of new members this year than in any previous year since the formation of the Association; three having been admitted at the March meeting held at Trowbridge, and seven to-day. On reading the report of our first half-yearly meeting held at Sherborne ten years ago, I find our number of members was then only 31. Now we stand at 74; or rather more than double the membership we had then. We are glad to know that death has not entered our ranks since we last met; but we have lost two valued members by removal to foreign parts. Mr. W. W. Monk, of Bournemouth, has gone to Melbourne, Australia; and Mr. Walter Thomas (who was with his father at West Cowes, Isle of Wight), to British Columbia. May they both prosper in their new undertakings. The latter gentleman has forwarded to our Honorary Secretary a few interesting particulars of his new surroundings, which will presently be read to the meeting.

A few months ago the theory of a new departure in the guide-framing of gasholders was ably discussed in the columns of our trade journals. The last few weeks have witnessed the successful, if only partial, accomplishment of this scheme. Mr. Livesey, with his accustomed energy and pluck, has made the experiment; and at the Rotherhithe station of the South Metropolitan Gas Company, a three-lift gasholder may be seen without the usual guide-framing beyond the second lift. May we not look upon this, and also the somewhat different plan invented by Mr. Gadd, and described by Mr. Newbigging in his paper read before the Manchester District Institution of Gas Engineers, as a type of what will in the future be the method of constructing and guiding our holders.

We have before us to-day three important subjects for consideration. Mr. Jervis has again kindly stepped forward to give us a few remarks upon “The Hydraulic Main, and Retort-Bench Bracing”—two points which have often tried the patience and ingenuity of many gas managers. Brickwork will expand with heat, and it is with difficulty that the hydraulic main, when placed on the beds, can be kept level, and so ensure an even dip in all the pipes; while the obstacles in the way of so bracing the retort-benches without exposing some portion of the tie-rods to a great heat are known to most of us. We hope Mr. Jervis will give us the true solution of this problem. Our old, but troublesome friend, naphthalene, will be alluded to by Mr. Davis, of Poole; and as he is going to tell us what he found to be a remedy for it, may all who are similarly perplexed try his plan, and obtain the same relief. Mr. Thomas, of West Cowes, has the happy knack of inventing new or improved appliances to meet the varying difficulties which are found in our works. A year or two since, he brought out a very capital “regulator” for tar-fires; while to-day he will describe “A Pressure-Gauge having no Joints.” Many of the pressure-gauges at present made, when used with foul gas, often clog in the small passages with tarry matter. Mr. Thomas has doubtless experienced this obstruction; and has improved upon the gauges already in use to remove this and other defects. I feel assured that the foregoing subjects, together with the usual business of the Association, will occupy all the time at our disposal; but should the opportunity occur, we shall be glad to hear remarks on any other subject calculated to advance the interests of the Association, that members may bring forward; a free interchange of opinions being essential to our well-being.

We cannot assemble at these autumn meetings without looking forward with hope, yet anxiety, to the coming winter. In the spring we are full of plans for improving our apparatus during the summer; but in the autumn these are largely completed, and waiting for the test of increased make and increased consumption.

All are hoping to sell more gas, and to manufacture, if possible, at a less cost. Trade seems to be somewhat improving throughout the country; and, if this is so, we trust it will mean a larger consumption of gas. Residuals, too, are looking up in every department; and we may hope to realize more from them than during the last winter. Some of you have ere this had your summer holiday, and are now braced up, and better fitted for the work lying before you. Others who have not will do well, if possible, to spend a few days in this popular watering-place of the west, and inhale the breezes from off the Atlantic Ocean. As the winter comes on, the conscientious gas manager has little time for recreation and change. All his powers of body and mind need to be concentrated on his work; for he must more or less unite in himself the various duties of engineer, chemist, and accountant, as well as take the general supervision of his workmen. Much wisdom and self-control are needed to carry on our different works successfully; and to those who, like myself, feel their insufficiency for these things, I would say in this, as well as in higher and more sacred matters, let us apply to the Fountain of all Wisdom, “who giveth to all men liberally and upbraideth not.”

Mr. J. J. JERVIS (New Swindon) read a paper entitled

THE HYDRAULIC MAIN, AND RETORT-BENCH BRACING.

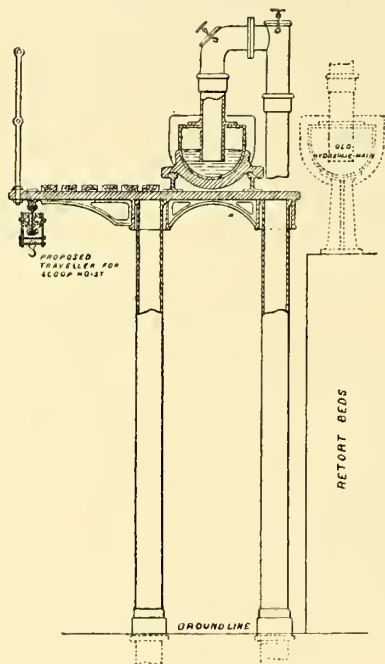

In the short paper I am about to read, I do not propose to enter into any matters relative to the sizes or shapes of the hydraulic main; or whether it should be of wrought or cast iron, or dispensed with altogether, and give place to a whole family of automatic valves, anti-dips, &c. I purpose only to speak of its position, or where it should be fixed by those who choose to retain it. Nearly all anti-dip disciples make use of the hydraulic; so that any discussion this question may raise will be of interest to them, and my sole object in reading a paper to-day is to form a text for some discussion.

The position of the hydraulic main is almost universally over the retort-benches—in a splendid place for all possible dirt, smoke, heat, and the general discomfort of the workman who have to attend to anything in connection with it—more especially in the pleasing duty of “pipe-jumping,” should chokes occur. Of course, the retort-bench offers a ready and inexpensive foundation for the hydraulic standards or crutches; but it may be open to question whether such a base as is offered by the retort-stack is the best for a reservoir which we desire to keep as level and rigid as possible. Some engineers contend that it is not objectionable for the hydraulic to be close over the retort-bench, and that the thick solid tar found in the vessel is not caused by the heat of the retorts. In “King’s Treatise on Coal Gas,” it is stated that: “Various means have been tried to prevent or clear out this accumulation of thick tar; one being an enlargement of the hydraulic itself, till, in one case that I [Mr. G. Livesey] have seen, each length would make a small Cornish boiler. Then the elevation of the hydraulic from two to four or five feet above the brickwork with the object of removing it beyond the reach of heat; it being considered that the heat from the setting converted the tar into pitch. A stream of gas liquor has in some cases been caused to flow through the main; and for a long time I had a quantity of hot water from the steam-boiler put into the main once or twice a week. But this did very little permanent good. The making the main deeper, and square at the bottom, has been suggested. Means for drawing off the tar from the bottom, instead of the top, have been devised and used with varying success; but by no plan, so far as I am aware, has the prevention of this accumulation been certainly or completely obtained. The causes of its production are twofold—first, the retention of the tar in the main; and, second, the heat of the gas from the retort in passing through this comparatively stationary tar evaporating its volatile constituents; for it is the hot gas, and not the radiated heat from the setting, that does the mischief.” And further on, after describing how, by making the hydraulic shallower, and only allowing about 2 inches of tar below the bottom of the dip-pipe, it states that the tar kept “perfectly fluid;” there was “no pitch or thick tar, and no crystals of ammonia; . . . not a stopped dip-pipe all the winter, and stopped ascension pipes were of much more rare occurrence.” Perhaps, then, it may be a fair argument to say that the choking of ascension and dip-pipes is not due to the close proximity of the hydraulic to the retort-bench; and that, therefore, on that account there is nothing to be gained by shifting it. Still I think the top of the retort-bench a most undesirable place.

Again, “King’s Treatise” says that the saddles or standards supporting the hydraulic should have a substantial bearing on the bench, and their position is over the piers separating the ovens. But is a substantial bearing obtained on those walls that are part and parcel of the beds, and shift accordingly with their expansion and contraction? These party walls need renewal at certain periods, and then there is anxiety and risk. Strutting, slinging, and other means are resorted to, to maintain the hydraulic in safety, which might be avoided were the main supported on girders or columns independent of the brickwork. This was chiefly the cause of my placing the hydraulic at our works on girders and columns in front and absolutely free of the retort-bench; so that any alterations or renewals of the brickwork could be carried out with perfect freedom from anxiety as to the safety of the hydraulic. The drawings I have here show how I have placed the main. It was done in a simple and cheap manner; the whole alteration, extending over seven beds of fives, costing under £40.

The idea of supporting the hydraulic other than on the brick work is not a new one; in fact, it is an old and condemned plan

In "King's Treatise" we find it stated: "The hydraulic main is usually supported by cast-iron stands or crutches . . . mounted on short brick piers, placed over the piers of the ovens, so that the main is at a short distance away from the front of the settings, and beyond the influence of the excessive heat. In the early period of gas lighting, the hydraulic main was cylindrical, and supported on cast-iron pillars, placed in front of the settings; but, owing to the prejudicial heat rising from the front of the bench when drawing the retorts, and the inconvenience of the projecting columns, this system is generally abandoned. From six years' experience, I demur to the indictment, both as to the prejudicial heat and the inconvenience of the projecting columns. The heat arising when drawing and charging is felt less on the platform than in the orthodox position of the hydraulic. The platform shown in the drawing is very handy for the workmen, and was much better for them than walking about on hot bricks. Anyway, whether the hydraulic is fixed over the brickwork or on girders, it is but due to the men that some provision should be made for as cool a platform as possible. The wooden battens of my platform are pretty dry by this time I expect, but they have not fired once during the six years they have been in use with the "excessive heat," although the platform is only 3 feet above the highest mouthpiece.

Having shifted the hydraulic main off the brickwork, I fancied there was not so much need to tie the piers between the beds by buckstaves back and front. The separate chimney system to each bed (which is now being tried, I believe, at Bath, and which we have followed for the past 14 years) interfered with bracing from end to end by angle-bars at the corners of the entire stack; and I could not, by placing buckstaves against the end walls of the bench, tie over the beds, as they were of different heights. Under the circumstances, I resolved to do without bracing at all; but whether or not the proceeding was wise remains to be determined. There is some consolation, however, in noting that in this matter as in others, there are divers opinions, and that there are some gas engineers who still do without bracing. Even in "King's Treatise" it is said that some "engineers contend that transverse tie-bars and buckstaves are unnecessary, because at times the bars are burnt away at the centre and the heat causes them to expand. But if the tie-bars are fixed in the proper position, either above the brickwork of the bench, or carefully embedded in it out of the reach of the heat of the flues, there is no danger of these burning away. Unless well bound together transversely as well as longitudinally, a bench will not endure the wear and tear of many seasons' working; the piers between the arches will inevitably bulge, and openings and crevices will appear between the ovens, admitting air and injuring the draught." Such is the text; and the matter of bracing seems to be so simple that there need be no fools.

There are one or two questions, however, that might be asked. Does not a long tie-bar—that is, from end to end of bench—allow of a good bit of expansion of brickwork? Except on account of the hydraulic main, do the middle or inside beds of retorts require longitudinal aid, inasmuch as they have the support of their neighbours one against the other? Is it sufficient therefore to buttress or otherwise stay the end beds only? And when an arch is taken down, is the temporary strutting on account of the hydraulic, or purely on account of expansion? Is the matter of checking the expansion by tie-bars a question only of how much? The heated brickwork *must* go somewhere; and the only consideration, I take it, must be which way? If the arches cannot spread, they must rise; and if the front walls cannot come forward, the rear ones will go backwards.

The point I wanted to decide was whether after all, when I had relieved myself of care in regard to the hydraulic, I need trouble

anything about bracing the retort-bench. I found from four years' experience without any bracing that the inside piers remained plumb; and the end one only went over about 2 inches in a height of 9 feet. The face ends of the pier walls had come forward about 3 inches, which would have been a bad thing for the hydraulic had it stood on crutches there. The expansion of the retorts, back and front, was not more than previously; but, altogether, I was convinced that some bracing is better than none at all, even though it be only from end to end over all. There will be more or less expansion with the best bracing; but there will not be the excessive expansion there is possible where no ties are made use of. The retorts "go" with the brickwork; and the cracks in them are not so readily repaired as in the walls, &c. I therefore determined to again brace up; but brace over all I could not. Mouthpieces at different levels in front, separate chimneys to each bed behind, and unequal heights on the top, precluded the use of long ties.

As in retort renewals I generally clear the arch right out, I wished to avoid all necessity of strutting, and have as clear and cool a working space as possible. I meditated some accommodating bracing. "Necessity is the mother, &c.;" and the drawing herewith shows my "invention." It may be thought complex and unnecessary; but, of course, I deem it just the thing. Anyway it has been satisfactory so far. Each bed is independent of its neighbour; and any bed may be cleared right away without occasioning any alteration of the tie-rod, &c. The short tie-rods will not allow of so much expansion as longer ones; and the placing back of the face of the bed 2 inches to form a corner for the angle-bar, does not interfere with the setting of the retorts. The "go" of the expansion of the retorts is directed by the angle-bars to the back wall rather than to the front; and the mouthpieces and ascension pipes consequently keep plumb. The cost of bracing the seven beds in this manner was under £45.

Discussion.

The PRESIDENT thought that the meeting had just heard a very practical paper. Mr. Jervis had given good reasons for removing the hydraulic to beyond the front of the retort-bench; and it seemed to have answered well in his case. At the same time, some managers were not much troubled with thick tar. At Trowbridge he had not cleaned out his hydraulic for several years; and yet had not found that thick tar accumulated to any considerable extent. He had personally inspected the arrangement described by Mr. Jervis, and could testify that the woodwork did not burr away.

Mr. W. FIDDES (Bristol) said he had tried to do without bracing with through settings, 20 feet in length; but they split and separated from the piers, at about 3 feet from the front of the setting. It was therefore necessary to put up buckstaves and tie-bars. He also found considerable improvement by putting on the top of the pier before turning the arch, a sort of "bond timber" made of very large fire-clay lumps, each about 2 feet in length, splayed to take the springing of the arches. The plan served to tie in the brickwork to a considerable extent; but not sufficiently so to dispense with the buckstaves and tie-rods. It was difficult to get buckstaves that would hold. The cast-iron ones would snap suddenly, without warning; and those made of wrought iron buckled and gave way gradually. Of course, as soon as a buckstave failed, it was necessary to renew it, or damage to the setting would speedily follow. When a setting was lit up, it expanded about 3 inches in the direction of the length, and 2 inches in height. So whenever the heat of the retorts was increased, the rule should be to slack the nuts of the tie-rods, and *vice versa*. In order to meet this variation, he had tried bell-cranks and a system of counter-weights to take the leverage. But this failed. Then he substituted lead, or lead and tin washers, thinking they might squeeze together gently. This, however, was not so successful as careful attention to the nuts, letting out half a thread or so each morning and night until the maximum expansion was obtained when lighting up. In cooling down, the furnace was filled with fuel, the damper shut, and the ash-pit and door carefully covered up, so that no cold air could enter. The retort-lids were all carefully screwed up; and when this plan was followed, two or three weeks elapsed before the setting got cool. The retorts lasted from 1200 to 1400 actual working days. When letting down, it was a good plan to seal up the mouths of

the retorts with 4½-inch brickwork, to prevent loss of heat; and the same might be done with new settings adjacent to those in use. For about 40 years he had worked with separate chimneys to each bed, very short, not more than 2 or 3 feet above the top of the stack. By this means, he secured better heats with less fuel; and therefore always adopted that plan.

Mr. J. LOWE (Weymouth) remarked that, having had great trouble with cast-iron buckstaves, even when "bellied" so as to be stronger in the centre, he hit upon a cheap and effective wrought-iron buckstave. It was made of two second-hand railway irons, strongly clamped together. The cost of these discarded rails was only about 80s. per ton for small quantities, and somewhat less for large; so that a 10-foot buckstave cost him about a guinea. Made in this manner they were about 5 inches square; so that with 14-inch partition walls, and retorts close to the side wall of the setting, it might be necessary to keep the ascension-pipes out a little, in order to clear them.

Mr. S. W. DURKIN (Southampton) said he had long been of opinion that some simple plan for bringing the hydraulic out from above the top of the stack was advisable. As at present fixed, it seemed altogether in the wrong place, particularly where there were long rows of beds. When letting some of the beds down, it was necessary to have the hydraulic main levelled; and the same when re-lighting, when working with the shallowest possible seal, as he was now doing, as the hydraulic should be perfectly level. Mr. Jervis's plan would enable the hydraulic to be kept level. Formerly he was much troubled with thick tar; but a few years since he adopted a plan, which he had already described to the Association, for taking off the tar from the bottom of the hydraulic. It was a simple arrangement, with no weir overflows. He used through retorts 20 feet in length, with a hydraulic at each end; and in both the tar was taken off at two points. He also made a connection between the hydraulic mains and the liquor-pump outside; and every day he pumped some liquor through the mains and overflows, and this washed away any accumulations of thick tar. By this means, also, the dips were sealed in liquor, and not in tar; the gas was washed by passing through the hot liquor; and the whole kept clear. Recently he had overhauled a hydraulic which had not been opened for two years; and found very little thick tar in it. Temperature had something to do with the formation of thick tar in the main, as there was a tendency in the direction in cold localities, when the main was over beds that were out of use. He was therefore pleased with the success of his arrangement, as saving the great trouble and labour involved in getting deposits of pitch out of the hydraulic. Referring to retort-bracing, he said that he remembered using nothing in years gone by but iron retorts; and these never strained the benches so much as clay retorts, which were brought more immediately in contact with the arches. In some settings of iron retorts, the tie-bars had actually been built into the brickwork; and when taken down for re-building, it was found that the tie-bars were quite carbonated and rotted away—being merely kept in position by the brickwork. He had used a rather ingenious form of buckstave. It was made of cast iron, with a groove in which a fish-plate of wrought iron was fitted. These were displaced by cast-iron T-shaped buckstaves, "fish-bellied" in section, which did not answer, as they were liable to snap suddenly with a loud report. Even when made thicker, and therefore stronger in section, this objection still obtained. Wrought-iron buckstaves were then introduced; and he had some that had been in use for 20 years. They were still perfectly sound, except at the lower end, where they were corroded by the water used in extinguishing coke. He had arranged a cast-iron channel to keep the water away and protect this part of the buckstaves. The tie-bars were nearly all on the outside of the brickwork—transverse as well as longitudinal; and he condemned the plan of burying tie-bars in brickwork. They should all be in sight. He quite agreed with Mr. Jervis that brickwork would "go" somewhere. If tied at the top, it would go at the centre; and if the transverse tie-bars held on, the walls would expand, and the bars would bend, but they would not break. He need scarcely add that if they did break, it would be a serious matter, and would destroy the draught and injure the retorts. Mr. Jervis's system of tying was interesting; but whether it could be adopted to through retorts, he was not prepared to say.

The PRESIDENT remarked that it was a pleasure to all to hear Mr. Lowe's voice again and to see him present again after his long illness and consequent absence from the last two meetings. In regard to the paper, tar at Trowbridge was taken off from the bottom of the hydraulic, and perhaps that was the reason why he had very little trouble with thick tar. He quite agreed that the bars should be outside the brickwork; and he had tried protecting them by enclosing them in drain-pipes, but still they would break off at the point of fiercest heat.

Mr. W. DAVIS (Poole) next submitted the following paper:—

A REMEDY FOR NAPHTHALENE.

Having been requested by our respected President to give a short extract from my experience as a manager, and as I consider it is the duty of every member of this Association to promote the interests of our profession by promulgating all the information he can, it has occurred to me that, by briefly stating my experience with that great pest to many gas managers—viz., naphthalene—I may interest, even if I cannot much instruct my brethren in the profession.

Some years ago I had the management of a works where there

were four purifiers 10 feet square; and they were fixed in such a position that the inlet-pipes from the hydraulic centre-valve had a fall into the purifiers. Consequently, when these were emptied, it was frequently necessary to clear the condensed matter from the bottom; and what made matters worse, the scrubber was a very small one—about 18 feet high by 6 feet diameter—through which ammoniacal liquor was continually being passed in the usual way. The distance between the scrubber and the centre-valve was only about 25 feet. Therefore, it was only natural that a large quantity of condensable moisture would be carried forward, and deposited in the bottom of the purifiers. In order to obviate this, as I happened to have four 16-inch pipes (12 feet long) in stock, I put them up in the form of a condenser. These pipes were fitted from bottom to top with 9-inch by ½-inch boards, cut in lengths of the diameter of the pipe, and placed cross-ways; thus giving a large rubbing surface for the gas in its passage to deposit the moisture carried forward from the scrubber. This, I was pleased to find, had the desired effect. It also produced an effect that I had not anticipated. I had previously been very much troubled with naphthalene; the inlet and outlet of the station meter having been frequently choked up with it, and also the pipes leading to the holders. The inlet and outlet pipes of the holders were likewise a constant source of trouble. After the introduction of these pipes (which I have since termed "depositors") I was not troubled with naphthalene. This led me to investigate the cause of the naphthalene formation. As many crystals contain what is termed the "water of crystallization," I at first came to the conclusion that I had made a discovery; but after consulting a very clever chemist, I found that these crystals do not contain that water. We then came to the conclusion that the crystals were produced by synthesis, and that the presence of moisture caused its production. Whether or not this is really the secret of its formation, it is a fact that, by carrying out this arrangement in works that I have since erected, I have not been troubled with naphthalene.

Discussion.

The PRESIDENT said that, speaking generally, naphthalene was not now so troublesome as in former years. He had known the inlet and outlet of the station meter to be choked in about a month, at a time when a part of the condenser had been out of use. But, by working the condenser regularly, and keeping the whole of it at work, he had not seen a stoppage with naphthalene for more than 20 years, although he had continued to use the same kind of coal and to work under similar circumstances. As to the effect on the public lamps, he remembered that once, after a continuance of hard frost and bright sunshine, on a certain Sunday night, the lamplighters could not light a single lamp in the main street. This was not due to naphthalene, but to moisture frozen in the pipes, and melted by the sunshine alternately; so that it gradually found its way to the bend at the bottom of the lamp-post.

Mr. J. H. CORNISH (Bridgwater) observed that some years ago he had much trouble with naphthalene; both the inlet and the outlet of the holder being choked. He employed steam to remove the deposit, and this caused the pipes to expand and occasioned a leakage into them from the inside of the tank, which could not be remedied without emptying it. A plunger was then used instead of steam, to clear the pipes; and this proved effective, at the same time dispensing with the disadvantage just named. He could recall instances when more than half the public lamps were out. But by adopting a large foul main, three times the length of the retort-house, and by more gradually condensing the gas, he completely got rid of trouble from naphthalene.

Mr. N. H. HUMPHREYS (Salisbury) remarked that there was no doubt as to the fact that naphthalene deposits were caused by improper or too rapid condensation of the gas; but he thought there were instances on record—some had been cited before the Association—of naphthalene being formed from gas that had been properly condensed and purified in accordance with the latest state of knowledge on these subjects. This seemed to support the view expressed by Mr. Davis, that under certain circumstances naphthalene might be formed by synthesis; and it would be interesting to have further information on the point.

Mr. R. BEYNON (Torquay) said he had not succeeded in completely overcoming the naphthalene difficulty, and was going to erect a larger foul main. In 1885 he was only troubled in the winter—from December to February. He had an ordinary annular condenser; and a friend advised him to cover it up during the next winter. In 1886, he covered it with sulphate-bags. This was effective to the extent that, whereas he formerly had a dozen complaints per day, they came down to one or two. But now he suffered mostly in the autumn between August and November, and most seriously in the mains and services. This he ascribed to the greater ranges of temperature prevailing at that period of the year. He read in the JOURNAL OF GAS LIGHTING, that Mr. Duxbury, of Darwen, had experienced much the same thing. He considered that it was to the regulation of the condenser that they must look for a cure.

Mr. H. G. CROWE (Wellington) remarked that he had a friend who was troubled with naphthalene. In this case the hydraulic main was carried down the centre of the retort-house; and there was a bench of retorts on each side—the one hydraulic serving for both sets of benches. His friend attributed the naphthalene to the position of the hydraulic. He inquired whether Mr. Jervis had found the alteration he had described in his hydraulic had any effect as to naphthalene?

Mr. JERVIS: I do not know what naphthalene is.

Mr. A. THOMAS (West Cowes) said that some little trouble from this source had fallen to his lot in times gone by. In the case of one particular length of main about half a mile from the works, every winter it would gradually fill up until the supply was entirely stopped. The first year he cut out a long length of the pipe, and found, to his surprise, that it was quite clear. The jarring had caused its dispersion. Afterwards he tried drilling a hole and pouring hot water down the main, which proved a cure. He also found that the application of a force-pump would remove it. But after he had started new works with a foul main and good condenser, he lost sight of the naphthalene. He therefore concluded that the foul main and the condenser furnished the cure; and that previously his gas had not been properly condensed.

Mr. S. W. DURKIN (Southampton) said that naphthalene was an old friend of his. The farmers complained of the present season, but more equable temperatures had prevailed, which were favourable to those who were troubled in this way. He was generally harassed by naphthalene in the autumn, or whenever great differences of temperature prevailed, such as alternations of bright sunshine and cold nights. Yet for nearly twelve months he had hardly known what it was. He had a set of men whose duty it was to attend to complaints of this sort, and he scarcely knew what to give them to do. Last winter he went on very well till after Christmas; and then he had a 16-inch pipe choked on the works, and this sorely perplexed him. This particular piece of main happened to be laid deeply in the ground; and he imagined there was some tidal influence which kept its surroundings cold and damp, and so caused the formation. He had a great belief in the foul main, and thought it possible that his present provisions in this respect were not large enough; and when a larger foul main was fixed, he hoped to see the naphthalene disappear altogether. As a proof of the fact that temperature had a great deal to do with the formation of the naphthalene, he might add that he never knew any to form near the station meter, which was kept at an equable temperature. Attention to this point, he believed, would avoid trouble at the meter.

Mr. W. FIDDES (Bristol) remembered that on one occasion several years since, he was with the late Mr. George Lowe in London when they were opening the ground to discover the cause of a stoppage in the gas-mains that supplied the Houses of Parliament. There was an 18-inch branch main, from which two 4-inch mains were taken off, and ran parallel to each other for some distance. One of these parallel mains was continually having to be stripped in order to clear away naphthalene, but not a particle was ever found in the other. He had had a great deal to do with naphthalene deposits himself, and was inclined to think that large main-pipes greatly reduced this pest. Some years ago they had smaller connecting-pipes about the works; but now it was the custom to use larger ones; and 24-inch pipes had been laid down in place of 9 or 10 inch. At one station it was the rule to clean out the inlet and outlet pipes of the holders every Sunday. He had known 7-inch holder connections completely choked, and 12-inch ones not much better; but now he used pipes not less than 24 inches in diameter for holder connections, and had not been troubled with naphthalene for a considerable time. In one particular case, a holder outlet-pipe remained perfectly clear for six years, and then choked suddenly; so that the gas could not get out of the holder. To remove it he used a small boiler, and a 1½-inch pipe carried down to the syphons inside. Some naphtha was heated in the boiler; and the vapour dissolved the naphthalene, and brought it down in a liquid state, so that it could be readily pumped out of the syphons. By this means the pipes could be readily cleared in two hours. He thought that the naphthalene formed over the top of the pipe something in the form of a mushroom; and after a time broke up and fell down the pipe—thus causing the sudden stoppage. The average temperature of the water in the holder tanks would be something like 56°; and he had observed that if the temperature fell much below this, they were sure to be troubled with naphthalene, if not in the holder connections, in the mains or services. The lights in the street lamps would be reduced to the size of rushlights; and the stoppage would, strange to say, follow regular lines in the direction of the points of the compass—running north-west one time, and in another direction at another time. Wherever the main was situated in low, damp, and therefore cold ground, he found the deposit take place. He also discovered that the deposit favoured points of junction of dissimilar metals—such as a lead service joined to a cast-iron main. It might therefore be questioned whether the magnetic influence of the earth, or electrical influences, had anything to do with the deposit. This, of course, was merely a suggestion. There was no naphthalene where canal gas was supplied; in that case it appeared to go into the tar rather than the gas. But where Somersetshire coal was used, it seemed to go into the gas. The subject was most complicated; and it was only by careful observation that a sure remedy could be discovered.

Mr. DAVIS, in reply, said he had often heard it remarked that a very short paper would bring about a good discussion; and it was a pleasure to him to see that the few remarks he had hastily thrown together, had elicited so much information. He thought his argument, that moisture was somehow concerned in the deposit, was fully borne out by the various speakers. Twenty years ago the theory was first propounded, that the tar and gas should be kept together in the foul main for a time, in order either to fix the naphthalene in the gas, or to take it out in the tar. He adopted this plan at the works where he was then engaged; but he left there before

the effect could be ascertained. He heard, however, that it was not altogether a success. At his next works the condensing and purifying plant was small in proportion to the quantity of gas made. He tried to reduce the moisture; and in so doing, decreased the naphthalene to such an extent that it did not give trouble anywhere except at the holder connections. Singular to say, the inlet choked in the spring, and the outlet in the autumn; but they never choked together. These were the facts; but he could not explain them. Perhaps in the autumn the heat of the sun had more power, and the temperature was higher; so that the naphthalene was vapourized and carried to the outlet. At this season of the year, too, it had been remarked that naphthalene was liable to form in the mains. Perhaps the heat of the sun vapourized the water in the holder tanks, which, being carried forward with the gas, aided or stimulated the formation of naphthalene. He did not know whether electricity had anything to do with it. It might have, as water would tend to convey electricity. But he had come to this conclusion: If the gas met with moisture anywhere between the retort and the burner, and was afterwards exposed to cold or damp, then naphthalene was formed. It would be remembered that M. Bremond had proposed to desiccate the gas by means of lime—a plan that was found effectual in preventing naphthalene.

(To be continued.)

THE "INDUSTRIAL" HIGH-POWER BURNER.

At the last Meeting of the Société Technique du Gaz en France, M. Potier introduced to the notice of the members a new high-power burner suitable for public lighting. It bears the name of the "Industrial" burner; and two forms of it are shown in the accompanying illustrations, which are taken from those which were given with the description of the appliance contained in a recent number of the *Journal des Usines à Gaz*. Fig. 1 is a type of burner constructed for a consumption of 15 cubic feet of gas per hour; fig. 2 is a larger one, consuming about 26 cubic feet per hour, and is shown fitted in a street lantern. The illuminating power of the former is 10 Carcels, or 95 candles; that of the latter, 22 Carcels, or about 210 candles. The special feature of the appliance is the covered chimney surrounding the gas-supply pipe, which starts from the bottom of the burner and issues above the

FIG. 1.

FIG. 2.

recuperator, or rather at the upper part of the chimney. Within the chimney there is set up a current of air, which keeps the gas inlet-pipe sufficiently cool to prevent any decomposition of the gas or obstruction of the tube and burners by soot. The recuperator, which consists of two concentric cylinders, A and B, connected by means of horizontal tubes C, is composed of nickel. The products of combustion meet in the cylinder A, whence they pass by the tubes C into the chimney D. The necessary supply of air is admitted by the openings E, and makes its way into the recuperator through a number of tubes F placed upon the two cones. The air, already partially heated by contact with the casing H, as well as by its passage through the tubes F, finally becomes superheated in passing to the exterior of the tubes C, which are arranged zigzag fashion, on its course to the lower portion or cup of the lamp G, where the burners are placed. The central pipe is protected from the action of the gas-flames by means of a porcelain tube I. To light the lamp, all that is necessary is to turn the tap into a certain position, and apply a taper to the lower end of the small bent tube shown in fig. 1, when the gas will burn at the top. By continuing to turn the tap, the group of burners becomes ignited, and the flash-jet is extinguished. The glass of the lamp may be easily removed for cleaning; and no shadow is projected by the lower portion.

THE LIGHT-GIVING POWER OF DIFFERENT GAS-BURNERS.

In the concluding notice of the papers read at the congress of the Société Technique du Gaz en France (held at Boulogne-sur-Mer in June last) which appeared in the JOURNAL for July 24, mention was made of a communication presented by M. Bouvier on the subject of the light-giving capacity of various kinds of gas-burners. The paper has since been published in full in *Le Gaz*; and from it we take the following particulars. The author's experiments were made with the burners generally in use; their lighting power being compared with the Bengel burner—the Paris standard. Each one was tested, by means of a Dumas and Regnault photometer, at a variable distance from the screen illuminated by a Carcel lamp, and under the conditions most favourable for each type of burner. The tests were made in the winter time, in a dark chamber of about 2100 cubic feet capacity, provided with a ventilating hood above the photometer; and there were never more than two operators present at one time. The consumption of 105 litres (3·7 cubic feet) of gas being that of the Paris standard burner, yielding the light of 1 Carcel (9·6 candles), the capacity of each burner is stated on this basis. Some of the principal results arrived at are given in the following table:—

Description of Burner.	Consumption per Hour in Litres.	Illum. Power in Carcels.	
		Actual.	Per 105 Litres.
<i>Open-Flame Burners.</i>			
Hollow-top steatite batwing, No. 7 of the large series used by the City of Paris, with regulator .	125·00	1·020	0·857
Larger burner (No. 8) of the same series.	200·00	1·740	0·912
<i>Argand Burners with Chimney.</i>			
Porcelain 20-hole burner (No. 4) .	189·00	1·980	1·100
London steatite Argand, 24 holes .	184·00	2·010	1·160
Porcelain 40-hole burner	171·90	2·100	1·233
Flat-top steatite 40-hole burner .	186·31	2·417	1·362
42-hole burner, with central disc .	286·40	4·000	1·466

By way of comparison, the author quotes some of the published results of tests of two gas-burners of the regenerative type—the Cromartie and the Wenham; and they show conclusively the superiority of this class of burners as lighting appliances.

Summing up his observations, the author states that the open-flame burners employed for the purpose of public lighting are capable, if they are judiciously selected and used, of yielding results within about 10 per cent. of those obtained with the Paris standard burner; while the enclosed burners of the ordinary and *quasi*-intensive types exceed the standard by from 10 to 45 per cent. One result of a test of the latest form of Clamond burner is given. This appliance gave a light equal to 4 Carcels with a consumption of 180 litres of gas, or 2·33 Carcels with the ordinary consumption of the standard burner.

Some trials of petroleum lamps were also made by the author. He selected two kinds of the "Lampe Belge;" each having circular wicks with flame-spreaders, and marked to give the light of 30 candles with a consumption of 90 grammes (1388 grains) of refined petroleum per hour. In one case "Solar" oil, at 80c. per litre retail, was used; and with a consumption of 70 grammes per hour, costing 5·63c., the light of 1·69 Carcels was produced. In the other, refined petroleum, costing 55c. per litre, was employed, as against an ordinary Carcel lamp burning purified colza oil at the rate of 10 grammes an hour, with the following results:—First hour: Consumption of oil, 87·7 grammes; light yielded, 3·01 Carcels. Second hour: Consumption of oil, 89·5 grammes; light yielded, 2·97 Carcels. Average consumption of oil, 88·6 grammes, valued at 4·87c.; light yielded, 2·99 Carcels. Of course, the price of the oil is subject to variation according to locality.

The result of the author's experiments shows that suppliers of gas may easily obtain the light of the Carcel with a consumption of 115 to 120 litres of gas by batwing burners (notably those used for public lighting) consuming from 125 to 200 litres of gas per hour; and an equal quantity of light with an expenditure of 80 litres of gas in the case of enclosed burners consuming from 200 to 250 litres per hour. The luminous intensity of the usual high-power burners is, as already shown, very great—the Carcel being produced with a consumption of only 40 litres of gas. Looking at this matter in the light of the competition of electricity and petroleum, the author points out the advisability of suppliers of gas making a judicious selection of the best burners for the use of consumers; this being one of the simplest and least expensive methods of retaining their patronage. If they can demonstrate that, by the employment of proper burners, the same quantity of light as is afforded by an ordinary incandescent electric lamp can be obtained with the consumption of 150 instead of 200 litres of gas—and the author's experiments prove that this can be accomplished—they will not have much cause to fear the competition of the newer system of illumination.

LIGHTHOUSE ILLUMINATION BY ELECTRICITY.

A correspondent has recently sent to *The Times* an interesting account of the electric lighting arrangements which have lately been completed and brought into operation in the magnificent lighthouse on St. Catherine's Point, in the Isle of Wight. It appears that prior to the 1st of May last the light exhibited at this station was described in the Admiralty list as a fixed dioptric light of the first order. In other words, it was a steady light pro-

duced by means of a six-wick concentric oil-burner and refracting lenses; the intensity of the naked flame being equal to about 730 candles. This, it may be mentioned, was a considerable improvement on the means of lighting employed when the lighthouse was first established in 1840, and when only a four-wick fountain lamp and inferior apparatus were in use; while before the last-named date there were only fires or lights on the downs above the Point—a kind of lighting which was both uncertain and unsatisfactory. At present an electric light is being shown, the full intensity of which was recently stated by Captain Sydney Webb, the Deputy-Master of the Trinity House, to be equal in illuminating power to rather more than 7,000,000 candles. Every half minute—for the light now revolves—a mighty flash of five seconds' duration, such as would have electrified the early navigators, sweeps around the sea, and is visible at distances that seem incredible. To effect this improvement, there has been added to the establishment a commodious engine-room containing three steam-engines of 12-horse power each, and two magneto-electric machines of the De Meritens type. Two of the engines are intended to work for lighting purposes, although only one is used in connection with one of the machines in clear weather. The third engine is meant to work the fog-signal, which, coincidently with the change in the light, has been greatly increased in power. In the lantern, carbons of very large sectional area (not circular, but fluted) are used; and the optical apparatus is of 16 sides or panels. As a precaution against breakdown, everything is in duplicate at least, with an oil-light in reserve as well.

In connection with the foregoing particulars, the writer gives a short sketch of the progress of coast illumination from the earliest attempts made to ensure the safety of the mariners by means of beacon fires. First, there was the wood pile on the lonely hill-top, possibly maintained at the instance of some humanely disposed individual; then the coal fire in the watch-tower, in a cradle of a peculiar disposition, closed at the top and towards the land, and open towards the sea, with iron bars in the nature of network, but without glass; then the tallow candles, three to the pound, as at Winstanley's Eddystone; then the flat-wick lamp supplied with sperm oil—the latter too great a luxury in these times—and aided by rude reflectors; then the cylindrical wick Argand lamp, supplemented by paraboloidal reflectors; then the concentric-wick lamps and lenses of Fresnel; and, finally, with optical apparatus improved both in design and manufacture, the Trinity lamps of Sir James Douglass, and the high-power gas-burners of Mr. Wigham—vegetable oil, mineral oil, and gas in the meantime coming into general use. It will be remembered that as the result of the exhaustive experiments in connection with the investigations into the relative merits of electricity, gas, and oil as lighthouse illuminants, conducted at the South Foreland a few years ago, and a full account of which, by Mr. Harold B. Dixon, M.A. (who was appointed to carry out the photometrical observations), will be found in the volume of the JOURNAL for the second half of 1885, the conclusion was arrived at "that, for the ordinary necessities of lighthouse illumination, mineral oil is the most suitable and economical illuminant, and that for salient headlands, important landfalls, and places where a very powerful light is required, electricity offers the greatest advantages." The most southerly point of the Isle of Wight, and, as such, one of the most important positions for a lighthouse on the shore of the English Channel, has been, it would seem, very properly selected for an electric light station. The only other lighthouses on the coast of England itself at which the light is produced by means of electricity are Souter Point, on the coast of Durham, between the mouths of the Tyne and the Wear, where the traffic by sea is thick and the smoke from the collieries and factories an element in the matter; the South Foreland, where the two lights, so well known to passengers across the Straits of Dover, were established as far back as 1634 for the then threefold purpose of leading clear of the Goodwin Sands, through the Downs, and up and down the English Channel; and at the Lizard, on the Cornish coast, where two more lights mark the southernmost headland of that part of the Channel—a locality which was earning an unenviable notoriety for wrecks during fogs. All these are powerful lights, allowing often a glare in the sky to be seen from far beyond the extreme range of the lights themselves. But, powerful as they are, they may be almost said to pale before the present St. Catherine's light; for it has ten times the intensity of the best of them—the one on Souter Point. In fact, it is one of, if not, as is believed, actually the most intensely brilliant light in existence.

DEATH OF MR. C. COPLAND, OF HULL.—We regret to have to record the death, on the morning of the 16th inst., in his 59th year, of Mr. Charles Copland, whose name was at one time closely associated with the gas supply of Hull. Mr. Copland was by profession a civil engineer; and some years ago he held an appointment in connection with the Phoenix Gas Company. In 1854 he relinquished this in order to become Engineer of the British Gas-light Company, of the whole of whose stations he had charge; and he then took up his abode in Hull. In 1870 he left the service of the Company with numerous testimonials, and joined Dr. Longstaff and his son in the management of the well-known firm of Messrs. Blundell, Spence, and Co. (Mr. Copland having married one of Mr. Henry Blundell's daughters). This firm was shortly afterwards converted into a limited liability company; Mr. Copland being one of the original Directors—a position which he resigned about five years ago on account of failing health.

Register of Patents.

TREATING NAPHTHALENE FOR USE IN CARBURETTING APPLIANCES.—Fenner, H. J., and G. H., of Blackheath. No. 14,085; Oct. 17, 1887. [11d.]

This invention relates to the arrangement of apparatus designed for use in the manufacture of naphthalene into convenient shape for filling into apparatus employed in carburetting gas for illumination; the intention being to mould it when in a molten state into "marbles, balls, or forms substantially round." The apparatus employed for the purpose consists of plates arranged in series (capable of assemblage and separation), in order to receive, form, and release the naphthalene supplied in a molten state thereto, in combination with means for applying pressure, guidance, and refrigeration.

REGENERATIVE GAS-LAMPS.—Walker, C. M., of Dulwich, S.E. No. 14,118; Oct. 18, 1887. [8d.]

This is an improvement on the lamps described in patents Nos. 7660 and 12,952 of 1887; the object of the inventor being to make a generator in the form of a single tube—preferably of a single casting of metal or other substance. Inside the generator is formed a collar to receive the chimney or flue, the bottom of which is solid, and pierced with a hole, through which the gas-supply pipe passes downwards. It also has lateral holes, connected to similar holes in the wall of the generator, for the passage of the products of combustion; the spaces between these connections being used as air passages. The outer casing of the lamp is fixed; leaving sufficient room for the passage of the products of combustion to the flue. Inside this is fixed a circular deflector extending somewhat below the seating of the glass door; and upon the end of the gas-pipe is attached a ring-burner having a double socket, as described in the earlier patent No. 12,952. In one form of the lamp, the air-tube of the burner is used to hold the glass door in its position by means of an under screw, which keeps the glass tight up against the rim of the outside case of the lamp.

GAS-LAMPS.—Boult, A. J.; communicated from G. Lebrun, and P. Fougeron, of Paris. No. 16,933; Dec. 8, 1887. [8d.]

The construction of these lamps will be understood from an inspection of the engravings—vertical sections of two forms of lamps.

The air necessary for the combustion of the gas in the lamp shown in fig. 1 is introduced into the globe B, and connected with a central vertical tube by horizontal tubes, the centre one of which is provided at the bottom with a perforated plate situated directly over the horizontal flame. The products of combustion are carried off by a chimney C surmounted preferably by a deflector. The burner D terminates in an elongated point or pin, which fits into a recess formed in the centre of the perforated plate through which the air passes to the flame. The burner proper consists of a ring of steatite or similar material, secured exactly in the centre of the apparatus, and concentric with the perforated plate. F is the plate on which the globe B rests, and into it is screwed the tube carrying the burner D; so that the height of it can be adjusted for the purpose of fitting the upper part of the lamp hermetically on to the globe at Z. The plate F is formed with two openings; one (in the centre) being screw-threaded for the reception of the burner tube, and the other for the purpose of lighting the lamp. This latter opening, when the lamp is burning, is closed by a moveable plate G formed with a similar opening. If it is desired to introduce the air necessary for the combustion of the gas from below the flame (as in fig. 2), the globe-carrying bracket F is perforated, and the air passes through the perforations and through a glass tube H into an upper chamber I, whence it descends to the flame through the perforated bottom of the chamber. To light the lamp, the bracket F is formed with an opening, closed either by a slide (as in fig. 1) or by a hinged door falling by its own weight. The centre of the parts of the lamp may be done by fitting the central tube K of the upper air chamber I into a corresponding recess formed in the metal part L of the burner.

ATMOSPHERIC GAS-BURNER.—Saul, D. H., of Shoreditch, London, E. No. 2324; Feb. 16, 1888. [6d.]

This invention relates to a form of atmospheric gas-burner (for heating asbestos or other fuel) especially applicable to slow-combustion grates. It consists of a bent air chamber or tube which passes under the bottom bar of the grate, and to which is affixed an oblong burner capable of being closed with a lid when required.

SUPPORTS FOR GAS-GLOBES.—Lake, W. R.; communicated from R. Jacobs, of New York. No. 10,355; July 17, 1888. [8d.]

This invention, relating to supports for globes and chimneys used in connection with gas or lamp burners, consists essentially (1) of a ring

sustained around the burner, and a series of spring slides adapted to move in guides on the ring, and having at their outer end suitable shoulders to catch the customary annular bead or flange around the globe or chimney; and (2) of the ring sustained around the burner, and made in two sections, adapted to be moved toward or from each other, and having shoulders to catch the bead at the lower edge of the globe, with suitable springs whereby the sections of the ring are given a spring tension toward each other and against the lower edge of the globe or chimney supported above or around the burner.

THE PRICE OF GAS IN OLDBURY.—According to one of the Birmingham papers, the gas consumers in Oldbury are greatly dissatisfied at the increase made by the Local Board in the charge for gas, as well as at certain conditions which the Gas Committee seek to impose upon their customers. It is stated that the proprietor of the Gaiety Music Hall, in Birmingham Street, has had the whole of his establishment fitted up with oil-lamps, and recently invited the tradesmen of the town to witness the effect. A shopkeeper in Church Street some months ago also discontinued the use of gas. These experiments with oil are being watched with a great deal of interest by a large number of tradesmen; and if they prove to be successful, others are expected to follow their example.

THE STRIKE OF GAS STOKERS AT SALFORD.—The strike of gas stokers at Salford, to which reference was made in the JOURNAL last week, terminated on the 17th inst.; a basis of agreement being arrived at by employers and men. A meeting of the Gas Committee was held in the morning, at which a deputation from the men was received. The matter was discussed, and a proposal laid before the deputation, with a view to meeting the objections raised. This was afterwards submitted to the main body of the men by the deputation, who attended a meeting of the Committee held in the evening at the Town Hall to communicate the views of the men upon the Committee's proposition. The proceedings at this meeting lasted for upwards of four hours; the result being, as above stated, that an agreement was arrived at. It was arranged that the men should resume work at six o'clock last Tuesday evening; and this was accordingly done. Subsequently, however, they complained that the duties were too heavy to be borne for any lengthened period. On Saturday morning, therefore, they appointed a second deputation, who had an interview in the Mayor's parlour with the Mayor (Alderman Dickens), Mr. H. Lord (Chairman of the Gas Committee), and Mr. Shonbridge (Gas Engineer and Manager). The conference lasted about half an hour, and resulted in the Mayor promising that a special meeting of the Committee should be called for yesterday morning to decide whether any alteration should be made in the present arrangement, and whether any further concessions should be granted in the men's favour.

GAS MANAGERS AND "OUTSIDE" ENGAGEMENTS.—At the meeting of the Smethwick Local Board last Friday week, certain matters affecting the Manager (Mr. B. W. Smith), which had been under investigation by the Gas Committee, were reported upon. It appears that Mr. Smith had been acting as professional adviser to Messrs. Lloyd and Lloyd, at the Coombs Wood works; but in doing so he considered he was acting within the liberty usually allowed to gas engineers. As he had expressed regret for having done this without the permission of the Committee, and stated that in future he would take care to confine his services solely to the Local Board, the Committee recommended that his action be overlooked. They further recommended that the Manager be instructed to take steps to at once reorganize his staff, in order to carry on the gas-works on the most economical lines. Mr. Brooks moved the reception of the report. Mr. Carr remarked that Mr. Smith had been for something like two years a salaried officer of Messrs. Lloyd and Lloyd; laying down their gas plant, superintending its erection, and attending to the manufacture of gas. He contended that this would take him away to a great extent from the business of the Board, for which he received a most liberal salary. He thought the Manager should have had more sense than to accept the appointment; and he felt sure that if he had asked the Committee to allow him to do so, they would not have given him permission. He moved, as an amendment—"That Mr. Smith either be requested to resign his situation as Manager of the gas-works, or that notice be given to him to do so according to the terms of his engagement." After some discussion, the amendment was put and lost, and the report adopted.

Correspondence.

GAS ANALYSIS.

SIR,—A few of the minor points referred to in my criticisms of Mr. Hicks's apparatus have been satisfactorily explained, but they are really of little importance; and in order to secure the adoption of the method, he should be able clearly to show some advantages over the apparatus in general use. There should be some undoubted gain in time, simplicity, or accuracy; and it appears to me that it would have been better if, in his original description, the writer had compared his results point by point with those obtained by existing methods, in order to demonstrate such advantages, if any.

Mr. Hicks requests me to explain the meaning I intended to convey by "a slight underpressure." The term is very common; but I will endeavour to make my meaning quite clear. Where levelling tubes are used, it is customary to lower the water-level somewhat to facilitate the collection of the runnings of the confining liquid from the sides of the measuring vessel. Fully three minutes should be allowed for this collection before taking a reading; otherwise the error at each reading may amount to 0.5 per cent. or more. Such an error would evidently affect the calculations; for in one of the examples given, there is an assumed diminution of 0.3 per cent. by absorption in the ammonia test, and if time were not allowed for collection of runnings, instead of the operation resulting in a diminution, there would be an apparent augmentation of (say) 0.2 per cent. I hope I have now made my meaning sufficiently explicit.

I believe it would be found that hydrogen and marsh gas could not be determined by this apparatus. It is obvious that ammonia, sulphuretted hydrogen, and carbonic acid must not be tested for in apparatus that necessitates their confinement over water—that is to say, where anything like an approach to accuracy is required; for one volume of water at 15° C. absorbs an equal volume of carbonic acid, which is the least soluble of the three, the volume of sulphuretted hydrogen absorbed being 3.23, and that of ammonia 727.20. The estimation of ammonia in coal gas with the best apparatus is extremely liable to error. In the present case the gas is exposed to water during collection of the sample, when regulating the water-lines, and also when standing to equalize the temperature. It may be for only a short time, as Mr. Hicks remarks; but it is long enough to vitiate his tests. Sulphuretted hydrogen has more exposure than ammonia; and the operation, besides being practically valueless, if carried out as recommended, spoils the remainder of the sample. Carbonic acid must also suffer sufficiently during its exposure, which is still more prolonged, to render the result incorrect.

Where the results can be at the most only approximately accurate, it would appear useless to take elaborate precautions, and make infinitesimal corrections. In fact, I cannot really see that the apparatus has any single advantage over the better class of apparatus in use, unless it be in the lowness of cost price—a matter not of much consequence.

Commercial Gas-Works, Stepney,

E. W. WHELDON.

Sept. 21, 1888.

ARMIDALE GAS COMPANY, LIMITED.—In the report presented by the Directors of the Company to the shareholders, at their half-yearly meeting held on the 31st of July last, they expressed their intention of reducing the price of gas, as from the 1st of the following month, to 13s. 4d. and 11s. 8d. net per 1000 cubic feet for lighting and cooking purposes respectively. The working of the undertaking in the six months ending in June resulted in a balance of £473. A dividend of 8 per cent. was declared; and it was decided to add £150 to the reserve fund.

THE PUBLIC LIGHTING OF TUNSTALL.—At the last meeting of the Tunstall Local Board, the Clerk read a letter received from the Defries Safety Lamp and Oil Company, Limited, containing an offer for the lighting of the town by oil in place of gas. The lamps were to be lighted at sunset and extinguished at sunrise, or within an hour thereof, for a period of three years, and each lamp to give a light, including reflected light, of 30-candle power; the cost to be £2 12s. 6d. per lamp per annum. The Company quoted Erith as a place which they had successfully (?) lighted, and where the lighting by oil was a great improvement on that by gas. The matter was referred to the Highway Committee. Subsequently the tender of the British Gaslight Company, Limited, for supplying the public lamps with gas for one year from Aug. 1, 1888, was accepted on the following terms:—£3 for every lamp supplied with a batswing burner; £4 10s. for every lamp having three batswing burners; and as to 100-candle power lanterns, to which a meter is attached, on an average consumption, at the rate of 2s. 4½d. per 1000 cubic feet, with additional charges of 13s. per lamp for lighting and cleaning, and 4s. 4d. per lamp per annum for reducing the light at 11 p.m.

STRATFORD-ON-AVON WATER SUPPLY.—Last Tuesday Colonel Ducat, R.E., one of the Inspectors of the Local Government Board, held an inquiry at the Town Hall, Stratford-on-Avon, with reference to an application of the Town Council for leave to borrow a further sum of £1700—making altogether about £22,500—for the purpose of water supply. Among those present were the Mayor (Sir A. Hodgson), Messrs. Lunn and Thompson (Councillors), the Town Clerk (Mr. T. Hunt), and other officials. Replying to the Inspector, the Town Clerk said that up to Lady-day last the Corporation had spent on the water-works exactly £21,368 12s. 8d. The expenditure had, in fact, exceeded the amount of loans already sanctioned, to the extent of about £900; and the Corporation found that it would require about £1700 to pay off existing liabilities, and provide for sundry expenses and the cost of connections and meters. The water-works were opened about two years ago; and although no compulsion was used, the consumption of water was increasing satisfactorily. The Inspector pointed out that the interest on the money already borrowed was between £700 and £800 per annum, which was considerably more than was derived from the water charges. Mr. Lunn said the balance was made up out of the general district rate. The Inspector inquired the total amount of loans already granted for sanitary purposes, and the assessable value of the district. The Town Clerk replied that the outstanding loans under the Public Health Act amounted to £33,787 1s. 6d.; and the rateable value of the borough was £31,678 16s., of which amount £27,376 12s. 3d. was for sanitary purposes. Occupiers of land paid only one-fourth of the rate levied on houses. After making other inquiries, the Inspector intimated that he would report to the Local Government Board on the subject of the application.

Legal Intelligence.

WESTMINSTER POLICE COURT.—THURSDAY, SEPT. 20.
(Before Mr. BIRON.)

CUTTING OFF A SUPPLY OF WATER.

Mr. J. Blackbeard, of 119, Brompton Road, applied to his Worship for advice respecting the action of the Chelsea Water Company, who had cut off the water supply to one of his houses, No. 5, Worcester Street, Pimlico; the tenant at the time having left not quite a fortnight, after an occupation of twelve years, and the rate being paid up to Midsummer last. Applicant had been himself supplied by the Company for 27 years; and the lady who had just left his house, after such a long occupation, had removed to another in the district, and therefore, continued to be a customer of the Company. No demand had been made; and, despite the remonstrance of a neighbour, the supply was disconnected, and an application directly afterwards made for 25s. to put the water on again. It was a most iniquitous, high-handed proceeding; and when he complained at the office he was treated with scant courtesy, and told that the best thing he could do was to pay the money. He had freely expressed his opinion that it was only a trick to put the landlord to the expense of having a stopcock fixed in the road or under the pavement, so that the officials would be in a position to exercise more control when they thought proper. This was the real secret; and he asserted that the Company only wanted the merest subterfuge or excuse to cut off the supply, being dissatisfied with the existing connections, for which the landlords had had to pay.

Mr. BIRON looked into the Company's Act and also the Water-Works Clauses Act, 1847, and then remarked that the question might be dependent on the interpretation of Acts incorporated with the Company's Special Act of 1852. The powers acquired by the Company under that statute were very large indeed; but it hardly seemed to him that section 59, which provided for cutting off a water supply, was applicable to such a case as had been stated. He could not, however, undertake off-hand to express a very positive opinion.

Applicant: While I was at the office, other people came in, and were equally dissatisfied with their treatment. We are nothing more nor less than in the hands of these great monopolist Companies; and they seem to do as they like with us. Surely the time has arrived for fresh legislation in the interest of the public. Cannot you order the Company to put on the supply again without the monstrous charge of 25s.?

Mr. BIRON: I say that I am inclined to think they have no power to cut off the supply; but I should certainly look at the Acts more carefully than I can do now, in the course of a busy afternoon, before I will issue process. I will look carefully at the law, and you can renew your application when I sit again. If I find I have the power, I will certainly exercise it.

Applicant thanked his Worship, but said he could not attend again as he was going to Scotland.

Mr. BIRON said if that were the case the question must remain undecided. All he could do, under the circumstances, would be to let one of the warrant officers wait on the Secretary of the Company, and ask him to be good enough to explain the reason of their procedure, and the section of the Act under which they had acted.

THAMES POLICE COURT.—WEDNESDAY, SEPT. 19.

(Before Mr. LUSHINGTON.)

CONVICTION OF THE EAST LONDON WATER COMPANY FOR REFUSING TO SUPPLY WATER.

To-day Mr. I. A. Crookenden, the Secretary of the East London Water Company, was summoned at the instance of Mr. John Henry Johnson, of St. Ann's Wharf, Limehouse, for refusing to lay on a supply of water to two houses belonging to him.

The evidence of the complainant showed that he had recently erected two houses in Northey Street, Limehouse. He had laid on the pipes and fittings in the usual way, and such as the Company had allowed him to use in 64 other properties within the jurisdiction of the Court. On the 25th of July he applied to the East London Water Company to have the water laid on, and paid the necessary fees and the rate, for which he held the receipts. The Company's men came to his place, and then went away again, without having connected the service. He had since repeated his application several times, but without success; and he then took out the summons against the Company. The reason given by the Company was that he had declined to put in cisterns. As there were already cisterns to the houses in question, and there were waste-preventing cisterns over the closets, he objected to storage cisterns. He had 64 cases in which the same thing would apply, if he was wrong on this point.

Mr. G. KEBBELL, who appeared on behalf of the Company, argued that they were within their rights, and justified in not giving complainant a supply, as he had not conformed to the several sections of the Act of Parliament bearing on the matter. The Act provided that before a supply was put on, a cistern to store the water should be fitted up; and if this was not done, they had power to discontinue the supply. The waste preventer did not hold more than two gallons of water. He called attention to the sections of the Act, showing it to be the intention of the Legislature that there should be a cistern, properly affixed, where there was a constant supply. He maintained that the contrivance which the complainant had put in was not a cistern. The domestic supply in this case was drawn from the main; while the complainant's vessel or receptacle was only for the closets. It was in the interests of the community that there should be proper cisterns affixed to each house, in case of a water famine.

Mr. LUSHINGTON held that the complainant's apparatus was a cistern with a waste-preventer inside it. Therefore, it was a sufficient receptacle for water, and complainant had a right to a supply.

For refusing to supply water on the 28th of August the Company were fined £5, and 20s. for each of the nine following days that the water was not connected; together with £1 1s. costs.

His Worship remarked that Mr. Kebbell might, if he pleased, apply for a case, and that the application would have due consideration if made within the proper time.

Complainant remarked that this would entail a great hardship on him.

Mr. KEBBELL observed that complainant would be sorry he had won the case by the time they reached the House of Lords.

OTTOMAN GAS COMPANY, LIMITED.—The Directors of this Company report that the gas-rental for the half year ending June 30 last amounts to £7424 7s. 8d., and the net profit to £2682 10s. 9d., which, added to the balance brought forward, makes the sum of £3156 2s. 11d., out of which they recommend a dividend at the rate of 7 per cent. per annum on both classes of shares. This will absorb £2625; and leave a balance of £531 2s. 11d. to be carried forward.

Miscellaneous News.

THE ASSESSMENT OF THE STIRLING GAS COMPANY'S WORKS.

In our Edinburgh Correspondent's "Notes" last week, brief reference was made to the appeal by the Stirling Gas Company against the raising of the valuation of their works and plant from £1300 to £1600, without, as the appellants contended, any change in the conditions of the undertaking to justify the increase. The matter was argued before the Valuation Court for Stirlingshire on the 10th inst.—Provost YELLOWLEES presiding—with the result, as already stated, that the amount was fixed at £1500. This is £100 less than the Assessor (Mr. Currie) arrived at; but as it is understood that the decision of the Magistrates is to be appealed against by the Company, a more extended notice of the proceedings than that given by our correspondent may be of interest to our readers.

Mr. R. WHYTE appeared for the appellants; and Mr. BUCHANAN represented the Assessor.

After a preliminary objection had been disposed of, the legal gentlemen and the Assessor had a private conference, which, however, failed to result in an agreement being come to as to the amount of the valuation, and the discussion of the case was proceeded with.

Mr. BUCHANAN, on the suggestion of Mr. Whyte, explained the principle on which the Assessor had fixed £1600 as the valuation of the works. He said that, under the Valuation Act, the Assessor was instructed to value subjects, where they were occupied by the proprietors, in such a way as to ascertain what they would produce if let to a tenant. The Stirling Gas Company had intimated to the Assessor, through their Treasurer, their total income. From this the Assessor had deducted the whole of the expenses which a tenant would take into consideration making an offer for a lease of the gas-works. The Assessor and the Treasurer had agreed in regard to the whole of the items to be deducted, with the exception of the Secretary's salary, Auditors' fees, allowance for gas-meters, and insurance on hereditary property. The salary and the fees were disallowed by the Assessor in consequence of the decision of the Court of Session in the Dundee case. The allowance for meters was refused on the ground that the income derived from them was not included in the total revenue returned by the Treasurer of the Company, and because, as a matter of fact, a tenant in taking the works, would not consider the question of meters at all—the gas consumers paying as meter-rent a sum sufficient to cover the outlay which the tenant would have to make in purchasing the meters. The insurance was disallowed, because the proprietors of heritable subjects were in no case permitted to deduct from the rent paid by a tenant, the insurance paid for the subjects.

Mr. WHYTE said that Mr. Buchanan's explanation had very much cleared the way and simplified matters, because it prevented the necessity of going over the whole case. Evidently the only difference between them was; first, whether the Assessor should allow the Secretary's salary and the Auditors' fees, amounting to £14 2s., as being part of the expenses of management; secondly, whether insurance was a proper deduction; and, thirdly, whether any allowance should be made to the Company for the meters as forming part of the floating capital of the Company. He also found, from Mr. Buchanan's explanation that the Assessor had gone on the principle laid down in the Falkirk Gas Company's case, decided by Lords Lee and Fraser, in the Court of Session Valuation Appeal Court, in 1883. The "rubric" of the case was short, and was to the following effect:—A private Gas Company, who were proprietors of their works and pipes, were assessed on the principle of deducting from the income derived from their customers the necessary expenditure, tenants' profits (estimated at 15 per cent. on two-thirds of the expenditure), and 5 per cent. interest on their floating capital. It was decided that this method of valuation was wrong. Lord Fraser held that the proper manner in which to value such a subject was to deduct from the income of the Company the annual expenditure, and a sum for tenants' profits, which ought to be estimated at a percentage on the net profits, and a percentage on capital invested in moveable property; the remainder being the annual value for the purposes of assessment. Lord Lee held that a percentage on the capital value of such works forms a fit, though not an exclusive rule of assessment, and that in the particular case an allowance of 8 per cent. on the capital value of the works would have been a proper method of valuation. Regarding the first and second heads, Lord Fraser, in the Falkirk case, said that the tenant was entitled to the following deductions:—The expenses of making and distributing the gas, of repairing buildings, gasholders, and mains, and of collection; charges incurred by the Company for management; insurance; interest on tenants' capital; and rates and taxes. It would be observed, remarked Mr. Whyte, that Lord Fraser specially mentioned insurance as being a proper deduction; and under the head of "Expenses of collection and management," the Secretary's salary and Auditors' fees certainly fell. The view which Mr. Buchanan took of insurance was, he considered, a very limited one. The insurance was not simply to provide against destruction by fire of certain articles of wood or other combustibles about the works, but to provide against explosion, which might happen in a business of the character of gas making. It had been found extremely difficult—in fact, almost impossible—to get an insurance company to take such risks without the payment of an enormous premium; and the Stirling Gas Company had established a fund for the purpose. If insurance was a proper deduction, as Lord Fraser said it was, it should be allowed, whether the premium was paid to an outsider or effected by a special fund. In the report of the Falkirk case, 1 per cent. was spoken of as a fair rate of insurance; and, considering the risks, it certainly was. On a capital of £15,000, 1 per cent. would come to £150; and this sum ought to be deducted for insurance. Lord Fraser specially mentioned meters as being part of the floating capital. He said: "A tenant, in order to carry on a works, must invest a considerable sum in moveable capital belonging to himself, upon which he was entitled to a percentage, which must be considerable, because of the perishable nature of the articles. For example, meters, which were in the possession of the Company, were moveables, without which they could not carry on their trade. The return from them could not be included in the annual value, because they were not heritage, as was decided in the former case of the Falkirk Gas Company; but these, though not included in the annual value, represent floating capital which an intending tenant must possess." In giving effect to his mode of deductions, Lord Fraser allowed 5 per cent. on the floating capital. The Assessor in this case only made an allowance upon £4000, which did not include the cost of meters, in which a capital of £6000 was invested. Apart altogether from the clear statement contained in Lord Fraser's decision, it was perfectly apparent that the business of a gas company could not be conducted without meters. They were moveable and not heritable; and hence were not liable to be taxed. He (Mr. Whyte) had prepared two statements—one according to Lord Fraser's opinion on the subject, and one based on the dictum of Lord Lee. According to the views of Lord Fraser, the assessable value of the gas-works would be £1235 1s. 5d.; by Lord Lee's method, it would be £1275.

Mr. BUCHANAN, in reply, pointed out that Lord Fraser gave his opinion that a Gas Company ought to be assessed very much on the principle laid down by the Judges in the Dundee case. Lord Lee, on the other hand, decided that the proper way to arrive at the valuation of gas-works—although it had not been done in any previous case—was that there should be a certain percentage on the capital value of the concern. Curiously enough, the result arrived at by both Judges was very much the same; but while it settled the assessment in the Falkirk case, it did not decide any principle, and the Falkirk case could not be quoted as an authority in the assessment of gas companies. On the other hand, the Dundee case was decided after a very elaborate proof and debate; and the Judges, knowing that their decision was to form the basis for valuing gas-works in future, considered the case, and issued a written decision, which was quoted at length in the decisions he had read.

Mr. WHYTE made a short reply, in the course of which he pointed out that the Dundee case, upon which the Assessor seemed to rely, was decided in 1881; and that in the Falkirk case, decided in 1883, the Judges had fully in view the decision in the previous case, and had agreed in holding it to be wrong, although they were not at one themselves as to what the right principle was. Immediately after the decision in the Falkirk case, the Assessor readjusted the valuation of the Stirling Gas-Works, on the footing of the principle laid down by Lord Fraser; but he seemed now to wish to depart from this, and fix some principle of his own. On the basis laid down by both Lord Fraser and Lord Lee, the valuation was excessive; and it was not for that Court to say the Judges were wrong.

Provost YELLOWLEES remarked that he did not think it was for them to say whether one Judge was right or another wrong, but there was a way by which they might arrive at a fair valuation; £15,000 was looked upon by all parties as a proper amount. This at 10 per cent. would be £1500; he moved that the valuation be fixed at that figure.

After some conversation on the subject, the motion was agreed to; the Provost remarking that, in framing their valuation so as to make the £1500, the Court had not fixed any principle.

ARBROATH CORPORATION GAS SUPPLY.

PROPOSED EXTENSION OF THE WORKS.

At the Meeting of the Arbroath Gas Commission last Thursday—Provost ANDERSON presiding—the proposed extension of the gas-works formed the subject of a long discussion. It will be remembered that at the previous meeting of the Commission (see *ante*, p. 346) a resolution to proceed with the extension of the works, at a cost of about £7000, was carried by a majority, on an amendment moved by Provost Anderson to a motion for delay; and that the opposition, through Mr. Michie, thereupon gave notice of a motion to rescind this resolution.

Mr. MICHIE (who read his speech) said his first reason for the action he had taken was that the Manager, Mr. R. S. Carlow, had assured the Board only recently, when the last of a series of permanent improvements on the works, costing from £5000 to £7000, was effected, that no further expenditure would be required for many years. Mr. Carlow's words at that time were that the Corporation were in possession of one of the finest little gas-works in Scotland. Yet now he came forward and asked them to be removed to another site, as the present one was unsuitable. Were they not astonished at this, after being told only 18 months before that the works were complete, and would not require anything for many years to come? His second reason for opposing the extensions was that he did not consider the proposed increase of storage accommodation at all necessary, and that they had never heard a word about defective pressure in the lower districts of the town until last winter. In conclusion, he moved, in the terms of his notice, that the resolution passed at the last meeting be rescinded.

Mr. SANDEMAN seconded the motion. He said the longer he considered the proposed extensions, the more he became convinced that they were unnecessary. In regard to the principal reason urged for the extension of the works—the insufficiency of pressure in the lower parts of the town—he had consulted several householders residing in the neighbourhood of the Harbour, and they had informed him that there was quite sufficient pressure there. Even the officials in the lighthouse had stated that they had an abundant supply of gas. He had obtained figures (which he quoted) showing that Arbroath stood in a favourable position, as compared with other towns, in the matter of storage accommodation; and in view of this he considered it useless to try to frighten the community into an expensive extension scheme by holding before them the possibility of the town being suddenly thrown into darkness through failure in the gas supply. He reminded the Commission that the consumption of gas was falling off, and that the result of increasing the expenditure on the works would inevitably be an increase in the price of gas. Gentlemen who spoke as if it were absurd to entertain the fear that the manufacturers in Arbroath would adopt the electric light, were not well read in what was taking place around them; for only the other day he saw a report which showed that the Forfar Gas Corporation had lost £275 during the past year by the introduction of the electric light into the factories. He knew also that the light had been adopted in factories in Brechin, Montrose, and Bervie, not to speak of Dundee, where it was extensively used in mills, factories, and building-yards. In view of these facts, the Commissioners ought carefully to consider what they were doing.

Mr. KENNY, while sympathizing with Mr. Michie and Mr. Sandeman in their objections to spending £7000 or £8000, moved, as an amendment, the previous question, as a protest against the method which had been pursued in bringing about the discussion. At the same time, he hoped that when the matter was sent back to the Committee of Management, they would see their way to postponing action until the spring months.

Mr. MELVIN seconded the amendment, characterizing Mr. Michie's conduct as void of common sense, and contrary to all the rules of fairness which prevailed in the carrying on of public business.

Mr. WILSON said he understood, when he left the country about a year ago, that the gas-works were fully equipped for a number of years to come; and therefore he was surprised, when he returned, to hear an expenditure of about £8000 spoken of as being necessary. He had looked into the matter very carefully, and had come to the conclusion that the works were by no means complete for two or three years' service. He did not impute blame to anyone, but considered that a mistake had been made somewhere. He was convinced that the Corporation must proceed with the extensions. He held, however, that the Corporation ought to provide a large depreciation fund to meet such heavy expenditure. He had full confidence in the ability of their Manager to carry out the extensions; and the mere fact that Mr. Carlow had been able to lower the price of gas in the face of a rising price for coals, was quite sufficient to meet all that Mr. Sandeman had advanced.

Provost ANDERSON detailed the various steps which had been taken leading up to the meeting that day, in order to show why the majority considered it necessary to carry out the additions to the works. Incidentally he pointed out that an estimate by Mr. Carlow, showing that new gas-works could be erected on a low-level site for about £15,000, had proved, even to Mr. Carlow's own mind, utterly fallacious, and had been abandoned;

it having been found that a figure nearer £30,000 would be required. Proceeding, he said it had been contended that the Commissioners would not, in the event of their resolving to remove the works, require an Act of Parliament to authorize their doing so. He admitted that they might adopt the Burghs Gas Supply (Scotland) Act; but even in the event of their doing so, he contended that they would not be entitled to transfer the debt and annuities from the old to the new works. Independent of all this, however, he held that if they were to get on with any business at all, they were bound to make up their minds what course they would follow; and they ought not to delay longer in carrying out the resolution of the Board, unless some particularly good reasons for rescinding it were given.

Mr. DICKSON, while expressing his intention to support the amendment, argued that it would be more economical to erect new works on a fresh site than to lay out money on extensions of the old ones. He adduced figures in support of his contention. He said the Commission had an opportunity now of getting rid of their admittedly bad site, and it might never occur again. There were plenty of places to be had; and he calculated that they would receive as much for the ground now occupied by the works as would purchase a new and more suitable site.

Provost ANDERSON pointed out that Mr. Dickson had not shown how he proposed dealing with the sinking fund in connection with the new works.

Mr. DICKSON held that it was not necessary for him to do so, as he did not propose that the old works should be abandoned all at once, but should be gradually absorbed in the new works.

Provost ANDERSON replied that this proposal was utterly unworkable, inasmuch as they could not, for example, have the retorts at the old site and the purifiers and other plant at the new one.

Mr. CLUNIE said the Sub-Committee of which he had been a member were thoroughly in favour of new works, on condition that Mr. Carlow's estimate of £15,000 was not exceeded, and that a suitable site could be obtained. The estimate, however, had been proved to be far under the mark; and the Sub-Committee had failed to obtain a satisfactory site.

Mr. MICHIE having replied, A vote was taken, with the following result:—For the motion, 5; for the amendment, 11. The resolution previously come to, to proceed with the works, therefore stands.

GLASGOW CORPORATION GAS SUPPLY.

OFFICIAL INSPECTION OF THE WORKS.

The official inspection of the Glasgow Corporation Gas-Works took place last Thursday; and the event proved to be of such considerable interest to the members of the Gas Trust generally, that it is not unlikely to become an annual one. In the early part of the day, Bailie M'Laren, who is at present the Acting Convener of the Gas Committee, together with a number of his immediate colleagues (Bailie M'Farlane, ex-Bailie Crawford, and others), visited the Dalmarnock works, over which they were conducted by Mr. W. Foulis, M. Inst. C. E., the General Manager of the Gas Trust, and Mr. Manwell, the Works Manager. Everything was found to be in a highly satisfactory condition there. The matter which received most attention from the Committee was the enclosing of a large additional piece of ground lately acquired by the Trust in the immediate vicinity of the works, for their subsequent extension. The party next visited the Tradeston works, which are about to undergo entire reconstruction, in accordance with the provisions of the Act of Parliament passed last session. Under the guidance of Mr. Foulis, the members inspected the arrangements involved in the reconstructural operations, including the new bridge which is to be built over the Caledonian Railway at Maxwell Road.

Later in the day the other members of the Trust, accompanied by various leading Corporation officials, left the Queen Street station by special train to join their colleagues of the Gas Committee at the Dawsholm works, which were to be inspected by the whole party and with some detail. Mr. Foulis was again the chief conductor; being assisted in receiving the visitors by Mr. David Terrace, the Manager of the works. Before proceeding with the inspection proper, the party partook of luncheon—Bailie M'Laren presiding, and Bailie M'Farlane occupying the vice-chair. The Chairman apologized for the absence of the Lord Provost (Sir J. King, Bart.) and ex-Bailie Ure, the Convener of the Gas Committee. The former, he said, was enjoying a well-earned holiday on the Continent; and the latter was suffering from illness. Referring to the official duties which the Committee and the other members of the Gas Trust were that day discharging, he remarked that the Committee had already inspected the works at Dalmarnock and Tradeston, and that the Dawsholm establishment, where they were assembled, was the largest and most complete of the gas-works belonging to the Corporation. In speaking of the magnitude of the operations carried on in connection with the Glasgow gas undertaking he stated that they carbonized 270,000 tons of coal per annum, and employed upwards of 2000 workmen in the height of the season; while the works as they stood were capable of producing 16 million cubic feet of gas per day. It was at present intended to expend about £160,000 in the erection of almost entirely new works at Tradeston; and, when completed, they were expected to be capable of making 10 million cubic feet of gas per day. In order to manufacture this enormous quantity of gas, 1000 tons of coal per day would be required. Obviously, it was a great advantage to have railway sidings at the works, together with all the appliances necessary for bringing forward and dealing with this large quantity of coal. The present producing power of the works at Dawsholm involved a daily consumption of 800 tons of coal. The works there were capable of being extended to double their capacity; and this showed that the Committee had great views in regard to the increase of the gas supply to that city. During the past summer there had been the most extraordinary increase that they had had for many years. He might safely say that it was 12 per cent. above the consumption last year; so that they had not taken steps too soon to provide for a larger supply than that of the present time. Subsequently the party, under the guidance of Mr. Foulis and Mr. Terrace, made a complete tour of the works; beginning with the gasholders, three in number, each 160 feet in diameter and 60 feet high, in two lifts, and having a total combined capacity of close upon 4 million cubic feet. The retort-house was next visited; and the Siemens system of regenerative firing was fully explained. The condensing, washing and scrubbing, and purifying departments were then inspected; and numerous points of interest were explained to the visitors as they passed along. The thorough removal of the ammonia in the scrubbers, and the perfect extraction of the carbonic acid, sulphuretted hydrogen, &c., in the purifying tanks, excited much curiosity in the minds of those Gas Commissioners who had not been previously initiated into the mysteries of gas making and purifying. The station meters, governors, exhausters, photometers, &c., afterwards received a due share of attention; and every one of the visitors was much gratified with the explanations given. Other portions of the works were visited; and then the party passed through the adjoining chemical works, which belong to the Gas Trust, but are leased to Messrs. Arrol and Co., for dealing with the residual products. With this the pleasant round of inspection terminated.

BRISTOL UNITED GAS COMPANY.

The Half-Yearly General Meeting of this Company was held last Wednesday, at the Offices, Canons' Marsh, Bristol—Mr. J. COLTHURST in the chair.

The notice convening the meeting having been read, the report of the Directors, the principal portions of which were given in the JOURNAL last week, was presented.

The CHAIRMAN, in moving the adoption of the report, said the Directors were pleased to be able to give the shareholders a favourable one at that meeting. The profit for the six months covered by it had been £30,628 15s. 3d., as against £21,140 in the corresponding period of last year. He desired to call their attention to the changes that had taken place since the year 1884, when a considerable reduction was made in the price of gas. Two alterations in price followed closely on one another; and it was found that the figures, which stood in June, 1884, at £30,645, fell to £14,951 in June, 1886. The shareholders would probably remember that their late Chairman, Mr. W. Spark, called attention to these facts, and pointed out that they had to draw upon their reserve fund to make up the dividend to the usual figure. Mr. Spark, however, expressed the belief that the figures would right themselves in time, that the Company would recoup itself, and that they would soon have a similar profit to that to which they had been accustomed. This prediction had been realized; for whilst in 1884 their profit for the half year was £30,645, in the past six months the sum stood at £30,628. So they would see that the figures were nearly similar. These figures were made up by the increased quantity of gas used and by the sale of residual products, which in 1886 were at their very lowest. The price of tar had improved somewhat; and with regard to ammoniacal liquor, while the price had not materially improved, the quantity had increased and made up the difference. The attention of the shareholders was also called in the report to the great economy that had been effected in the expenditure. He found that although they had used more coal during the past six months, yet, through the changes that had taken place in regard to freights, they had effected a considerable saving. Less material had been used in the works, less money had been spent on the mains, and less in wages; and all these economies had helped to make up the substantial difference shown in the report. The Board also, feeling the desirability of increasing the use of gas for other purposes than lighting, held a public exhibition of gas cooking and heating apparatus at the Drill Hall, Clifton. The show was an excellent one; and as the result of the exhibition, their supply of cooking-stoves had risen to upwards of 700. This had naturally increased the supply of gas. The Directors had to record the retirement of Mr. Walter Fiddes, who for 44 years was in their service as Engineer; and they had voted him a retiring allowance of £500 per annum. They had found it necessary to considerably alter their arrangements in regard to the duties at their several stations; and, as a necessity, it was thought desirable to make a change in regard to the Chief Engineer. It was felt that, as Mr. Fiddes had served them so long and so well, upon his leaving them he should be awarded a retiring allowance, as was done in the case of their former Engineer; and the sum fixed upon was £500. In the report they saw that it was proposed to rescind a resolution of 1853, which fixed their meetings for March and September, in order that they might be held in February and August. He explained that formerly their collections were made half-yearly. But recently they had altered their system, and had the collections made quarterly; and the change enabled the Directors to declare the dividend at an earlier period than usual. It was proposed now to hold their meetings about a month earlier than they had been accustomed to do.

Mr. S. JONES seconded the motion, which was carried unanimously.

On the proposition of the CHAIRMAN, seconded by Mr. JONES, a dividend at the rate of 10 per cent. per annum was declared.

The CHAIRMAN next moved—"That the resolution passed at the half-yearly meeting of proprietors on Aug. 5, 1853, by which it was decided that the half-yearly meetings of the proprietors should be held in March and September, be now rescinded."

Mr. R. W. GILES seconded the motion, and it was adopted.

Mr. J. C. WITHERS asked whether there was a prospect of the price of gas being further reduced.

Dr. TUCKETT moved a vote of thanks to the Chairman and Directors for their attention to the affairs of the Company. The balance-sheet was, he said, the best the Directors had issued for a long time.

Mr. H. J. ALLIS, in seconding the motion, spoke of the very satisfactory profit made during the past half year.

The motion having been agreed to,

The CHAIRMAN replied, saying that his colleagues and himself appreciated the kind expressions used towards them, and that it would stimulate them to increase their efforts on behalf of the shareholders. With regard to the question as to further reducing the price of gas, he would point out that the Directors were in the position of trustees between the shareholders and the public; and although it was their duty to secure for the former the 10 per cent. dividend, they also felt that, in whatever way they could possibly improve the quality of the light and lower the price, it would always conduce to the interests of the undertaking to do so. Without giving any specific answer to the question, they might be assured the Board would not lose sight of the matter.

The proceedings then terminated.

WATER SUPPLY IN THE FEN DISTRICT.—At the meeting of the Holbeach Board of Guardians last Friday, a resolution was passed approving of the South Lincolnshire Fen Water Act, passed last session, and expressing an opinion that the supply of water would be a great advantage to the inhabitants of the Union, and that the Rural Sanitary Authority would do all in their power to encourage the scheme.

SCHEME FOR THE SUPPLY OF WATER TO HOLYWELL.—Last Tuesday evening an important meeting was held at the Assembly Hall, Holywell, when the claims of a scheme for supplying the large and populous district embraced in Holywell, Greenfield, and Bagillt were advocated by several well-known gentlemen. A Company has been formed, with a capital of £20,000, to carry out the scheme; and assistance has been promised by the Duke of Westminster, the Earl of Denbigh, Lord Mostyn, Sir Piers Mostyn, and other prominent landlords. The source of the supply is Milwr, about 1½ miles from Holywell; and the water, after passing through filter beds, will be stored in two large reservoirs. The Engineer of the scheme is Mr. H. E. Taylor, C.E., of Chester, who was engaged in a similar capacity in connection with the Hawarden Water Company; and he considers it likely to be a very successful one. Alderman W. Brown, Mayor of Chester, presided; and among the addresses was one by Mr. C. E. Matthews, of Birmingham. He strongly urged the inhabitants to support the scheme. He pointed out that it was the last one likely to be brought forward; and if not accepted, the Board of Health would provide a proper supply of water and charge it on the rates, as the present supply had been condemned by them. A resolution was passed approving the scheme, and a number of shares were afterwards subscribed for by the tradesmen and inhabitants.

THE PRICE OF GAS AT ROCHDALE.

A Meeting of the ratepayers of Rochdale was held last Thursday, for the purpose of discussing the general rating of the borough, and protesting against the recent increase of the salaries of certain Corporation servants. The following resolution was moved and seconded:—"That this meeting is of opinion that the past expenditure of the borough is extravagant; that, in the interests of the ratepayers, a revision of the existing financial arrangements is urgently needed; and that the price of gas should be substantially reduced to local consumers." Attention was called to the fact that the price of gas is 3s. 2d. per 1000 cubic feet in Rochdale, and only 2s. in Bury; and it was contended the surplus was to a large extent illusory, and at all events ought not to be left to the Corporation to be used in some extravagant manner. Alderman Taylor, replying to the mover and seconder of the resolution, said the price of gas had been steadily reduced in the town. When he first began to consume gas, it was 14s. per 1000 cubic feet. Then it was reduced by degrees to 12s., 10s., 8s., and at last to 6s. It was also decided that whenever the profits should reach or exceed 5 per cent., another reduction should take place. This had been done whenever possible. What was the position? There were carbonized at the gas-works between 30,000 and 40,000 tons of coal every year, for which about 9s. per ton was paid. A year or two ago the price was 10s. If a rise of 1s. per ton in the price of coal—and it was quite possible that this might occur—took place, what would be the result? Suppose, for instance, 40,000 tons of coal were consumed, a rise of 1s. per ton would amount on the whole to £2000. In that case they would not have their 5 per cent. At present the supply of gas to the public lamps was not paid for; it was given. There was another benefit which the inhabitants of Rochdale possessed. When the gas-works were purchased, a great effort was made to ensure the poorest cottager being provided with gas. There were now in Rochdale nearly 20,000 meters at work; and leaving the factories out of the question, the population to be supplied was 80,000. There were more people in Rochdale supplied with gas than in almost any other town in Lancashire, or perhaps in England. Another advantage the town had had recently was in the treatment of residuals. The Council had not been extravagant at all in the matter of the gas undertaking; but had been very careful in the expenditure. He was anxious that the ratepayers should not at one coup reduce the price to anything like the charge at Bury. The Gas Committee had recommended the Council to reduce the price, and he believed a further reduction would take place. But if the town did get a reduction, and they had no profit whatever, would they willingly pay the £14,000 a year loss on the water undertaking? They had to do it. [A VOICE: "We must take it off the salaries," and loud cheers.] Why, the whole of the salaries would not amount to this sum, nor half of it. It was a poor way of economizing to pay one's servants a less sum than they were worth. Mr. E. Nuttall contended that the Corporation could reduce the price 7d. per 1000 cubic feet, and still make a fair profit. Mr. Allan Mills pointed out that this would mean an increase of the rates to a corresponding amount; but it was most desirable, in the interests of direct taxation. If any ratepayer wished to avoid paying the 1s. 3d. in the pound, the amount of which he was relieved by the gas profits, he had only to make use of some other sort of light. The owner of a large warehouse rated at £100 per annum would perhaps only expend £2 annually in gas. The effect of this would be that the large ratepayer would get out of paying 100 one-and-threepences in the pound, because his rates were reduced by the profits on the gas. And who were paying these rates? The cottage consumers. It was unfair that any man in the town should be able to avoid paying in this manner. Mr. H. Cunliffe held that the larger consumers really produced the profit. Mr. E. Evans stated, on the authority of a member of the Gas Committee, that the tenders for supplying the Rochdale Corporation with coal for making gas, when before the Committee, were not dealt with, or entered into, in a businesslike way. It was stated by his informant that the very same class of coals as those accepted were offered by another tenderer at 1s. per ton less. The resolution was passed with a few dissentients. The following resolution was also carried:—"That this meeting strongly condemns the action of the Town Council in their recent increase of official salaries, in defiance of the wishes of the ratepayers as expressed at the meeting held in the Town Hall, and pledges itself not to support any candidate at the forthcoming November elections who voted for those increases, and who thus set the ratepayers at defiance."

RIO DE JANEIRO GAS SUPPLY.

It will be in the recollection of our readers that about two years ago the gas supply of Rio de Janeiro was transferred by the Brazilian Government from the English Company who had for a number of years held the concession to a Belgian syndicate; the works being handed over to the latter body on the 1st of September, 1886. We have received some extracts from a report which has been presented to the Minister of Commerce, Public Works, &c., by the General Inspector of Gas Lighting, in regard to the lighting of the city during the past year; and we take therefrom the following particulars:—The Inspector states that the new conditions under which gas is supplied are advantageous both to the State and the private consumers, not only in the matter of price, but also in regard to the quality of the lighting, which has been improved. The consumption of gas in the street lamps, which was formerly 95.5 litres (about 2½ cubic feet) per hour, and for which the Municipality paid 6.8 centimes (0.068d.), is now 100 litres, which cost 6.4c. The Public Departments and private consumers paid respectively 70c. and 75c. per cubic metre of gas (15s. 9d. and 16s. 10d. per 1000 cubic feet) under the old arrangement; but under the new one they do not pay more than 60c., or 13s. 6d. Comparing the prices charged under the old contract with those of the new, as applied to the total consumption of gas last year, the economy effected is stated to amount to the sum of 204,927 frs., or about £8000. The increase in the consumption of gas during the year was 11.12 per cent.; being 2.5 per cent. for public, and 8.7 per cent. for private lighting. The additional private consumption was caused by 631 new customers, and was quite a natural result of the reduction in the price. Under the new arrangement, the intensity of the light has also been increased to the extent of more than a candle; and this higher illuminating power, it is stated, has always been kept up. Certain complaints have been made on the subject of this increased intensity, as not being that prescribed by the contract, and as necessitating the employment of twice the number of private burners to obtain the same quantity of light as that furnished by the English Company. These complaints, the Inspector states, have no foundation; and seeing that all the gas supplied is of the same quality, the light produced by the street lamps cannot be greater than that found in the private houses. For the outlay of all the consumers to be double, the Company would have to manufacture twice the quantity of gas which was actually distributed; whereas the meter at the works shows an increase of barely 8.27 per cent. upon that of the previous year. It must therefore be to other causes that the complaints must be attributed. In the first place, many leakages exist, due to the bad workmanship of the gas-fitters; then, secondly, burners are employed of inferior quality. In order to avoid complaints, however, and to enable the con-

sumers to obtain a good light with economy, the new Company supply and fix gratuitously burners of all sizes, selected with great care. The Inspector points out that most of the inhabitants fail to give sufficient attention to their daily consumption of gas; and some even compare the bill for a winter quarter with a preceding three months in the summer season. Finding the former higher than the latter, they at once make a complaint, without having noticed the difference in the length of the nights. A great number of these complaints against the new Company are of the same nature as those brought forward in the time of the English Company, and are quite familiar to the Government. Certain irregularities have, nevertheless, been discovered; and these have necessitated the intervention of the Lighting Inspector.

THE PRICE OF GAS IN LANCASHIRE.

The Borough Treasurer of Blackburn (Mr. J. H. Bailey) has lately published an important and comprehensive return relating to the finances of Lancashire towns, from which the following particulars are extracted:—

Name of Place.	Popula- tion.	Rateable Value.	Total Rates in the Pound.	Price of Gas.			Gas Profits.	
				Small Cons.	Large Cons.	Dis- count.	Total.	Equals a Rate per £.

THE PUBLIC LIGHTING OF CHELSEA.—According to the report of the Chelsea Vestry for the year ending March 25 last, the total number of lamps in the whole district was 1346; the price of gas being 2s. 5d. per 1000 cubic feet. The new lamps erected during 1887-8 numbered 13, and 15 were discontinued. There were 1907 defective lights reported to The Gaslight and Coke Company, of which 825 were caused by deposits of naphthalene and 72 by water. The number of repairs to lamps and lanterns was 1566. In the Vestry's testing-room, 330 governors were tested during the year.

ANGLO-GREEK PETROLEUM WORKS AND WELLS COMPANY, LIMITED.—This Company was registered last week with a capital of £300,000, in £10 shares, with the objects of acquiring certain properties and concessions of petroleum wells situate in Greece; working, letting, selling, or otherwise dealing with the same, or any part thereof; carrying on the manufacture of all the products drawn from the wells, and the petroleum trade in all its branches; manufacturing gas, and carrying out gas-works of every description; making railways, tramways, roads, or other means of carriage or conveyance, piers, landing-places, and other works and buildings incidental to the Company's business.

THE NEW WATER SUPPLY AT BURNHAM (SOMERSET).—It is satisfactory to know that the inhabitants of Burnham, who agitated so long for an improved water supply (and apparently not without good reason), are showing their appreciation of the new works which the Local Board have just had constructed at considerable outlay. At the meeting of the Board held last Thursday, it was reported that the residents were applying so fast to have the water laid on to their houses that the Surveyor could scarcely keep up with the demand. Already 309 houses out of 499 have been connected. The people are now beginning to admit that there was no good well water in the neighbourhood; and they acknowledge that the source whence the Board derived their supply—the Winscombe Springs—is the best available.

METROPOLIS WATER SUPPLY.—In the course of their report to the Official Water Examiner for the Metropolis (General A. De Courcy Scott, R.A.) on the composition and quality of daily samples of water supplied to London last month, Messrs. Crookes, Odling, and Tidy say: "As might have been expected, the unusual and irregular meteorological conditions of the past few months have had a certain influence on the waters of the Thames and Lea. We shall have to comment on this circumstance hereafter. We content ourselves now with remarking that the water supplied to London during a very exceptional summer has been uniformly good and wholesome. Of the 182 samples examined by us during the month of August (excepting three samples of the East London Company's supply which were recorded as 'very slightly turbid'), the whole were found to be perfectly bright, and free from any trace of suspended matter."

CHELTENHAM GAS COMPANY.—At the half-yearly meeting of this Company held last Thursday, the Chairman (Mr. W. H. Gwinett), in moving the adoption of the Directors' report, said that the accounts for the past six months were very satisfactory; the profit realized admitting of the payment of the usual statutory dividend. The revenue had increased, and so had the profits, as compared with the corresponding period of last year. This was due partly to additional consumption, reduced working expenses, and the adoption of improved manufacturing processes. The new gas-holder in course of erection was practically finished, and was at present under test, previous to being brought into use during the coming winter. On behalf of the Directors, the Chairman expressed their indebtedness to Mr. R. O. Paterson, their excellent Engineer and Manager, under whose superintendence the holder had been constructed. A question was asked as to the proposed adoption of the electric light in a portion of the borough, and whether any communication on the subject had been received from the Town Council. The Chairman said there had been a communication, and the matter was receiving the attention of the Directors. The report was adopted; and the full statutory dividend having been declared, the meeting was brought to a close.

PROPOSED CONSTANT WATER SUPPLY IN THE CITY.

At the Meeting of the Court of Common Council of the City of London on Thursday last—the Lord Mayor (Alderman P. De Keyser) in the chair—a lengthy report was presented by the Gas and Water Committee upon the petition of St. Giles's Vestry, Cripplegate, and letters from three other parishes in the City, asking the Corporation to direct the issue of notices calling upon the Water Companies supplying the City to provide a constant supply of water. The report stated that the New River Company had expressed their willingness to confer with the Special Sub-Committee, and subsequently the Sub-Committee were informed that the Company were willing to give the constant supply if required, provided the regulations of the Metropolis Water Act, 1871, were previously complied with. It was ascertained that the average cost in St. Pancras in altering fittings, &c., was £5 for each owner; but that the cost in the City would probably be more. The number of fire hydrants would also have to be doubled. The Sub-Committee had reported further that they had received a letter from Mr. Archibald Dobbs, who stated that the citizens would regret it if the petition in favour of a constant supply were granted. Mr. Dobbs afterwards attended before the Sub-Committee, and gave additional information. The report stated that very few complaints reach the New River Company as to short supply—on an average, about two a day; and these were usually owing to a defect of some fitting or the stopcock being shut. Resolutions in favour of the constant service had been received from six parishes; four had sent resolutions against; and four had passed resolutions in favour, without communicating the fact to the Committee. Thus only 15, including Cripplegate, out of the 112 City parishes had expressed an opinion on the subject. The Committee believed it would be obviously unfair to apply the constant service to the City generally; and they suggested that, if it were decided to adopt it at all, it should be only to those parishes which had expressed a desire for such supply. The Committee recommended that it was not expedient, in the interests of the petitioners and the citizens generally, to take any steps in the direction indicated.

Mr. H. MEAD (Chairman of the Gas and Water Committee), in moving the adoption of the Committee's report, said that out of 14 of the 112 parishes of the City, ten were in favour of a constant water supply, and four against. The remainder of the parishes had expressed no opinion. The parishes in favour of a constant supply constituted a very small number of the ratepayers to set such large machinery at work, which would affect 35,000 inhabitants by putting them to great expense. The Committee had taken the matter into very careful consideration; and had had an interview with the Water Companies, who informed the Committee that they were quite willing to give a constant supply, provided all the requirements of the Act of Parliament authorizing it were complied with. The Companies also stated that, under certain circumstances within their power, they would supply individual firms with a constant supply for the purposes of trade or otherwise. The Committee had also considered the advantages and disadvantages of a constant water supply, and had come to the opinion that the disadvantages outweighed the advantages. The ratepayers would be put to considerable inconvenience and expense; the cost of the new fittings being estimated for the whole of the City to amount to something like £300,000 to £400,000. The report showed that the average cost of the fittings necessary for a constant water supply in St. Pancras was £5 for each house. This, he thought, perfectly justified the Committee in coming to the conclusion not to recommend the Court to agree to the application of the memorialists.

Mr. R. STAPLEY observed that the Committee had no document or letter from the Water Companies in which they agreed to give any individual firm a constant supply. The Committee, however, made a point of a promise to this effect from the Companies. Now he (Mr. Stapley) had made an application on the strength of the Committee's report to the Company that supplied his district; and they denied having made any such promise. Therefore one of the great arguments put forward by Mr. Mead fell to the ground. It also seemed to him (Mr. Stapley) that Mr. Mead was very much out in his estimate as to the expense of the fittings for a constant supply. The Vestries, he believed, would very soon report favourably on the constant supply system, because of the great convenience this would be to a large number of persons in the City. With a constant supply, they would be able to turn off their water at night with the certainty of being able to turn it on again early next morning, and not, as now, have to wait sometimes till 11 or 12 o'clock in the forenoon. He would be the last to urge the Corporation to put the City to a great expense for new fittings if the inhabitants decided against it; but the Companies should be made to understand that, if they would provide a constant service to individual firms who requested it, a good deal of the objection to the Companies would be removed. The Company he spoke of, however, distinctly denied making any such promise as the Chairman of the Committee had mentioned.

Mr. H. H. BRIDGMAN said the chief point in the Committee's report was the great expense for new fittings. It was not the Water Companies' business to inform people what the cost would be; and he was sure that, if any individual firm or parish desired a constant supply, the New River Company would give it, provided the requirements of the Act were complied with. Seeing that only a few of the Vestries had asked for it, he thought the Committee were quite right in their report not to recommend the Court to put the whole City to the expense of new fittings. The Corporation, under the circumstances, should not apply their powers to make the New River Company afford a constant supply, because, although it had been stated that £9 or £10 would be the cost of new fittings, he found in one instance the cost was £50.

Mr. H. GREENE observed that the parish of St. Giles had come before the Court of Common Council in 1885 and again in 1888, asking the Court to take the necessary steps to call upon the Water Companies to give a constant supply to the inhabitants of the City. Had they requested them to do this for their own particular parish, the Court would have dealt with it in a very different manner; but as they desired the Court to put their powers in motion for the purpose of a constant supply to the whole of the City, they had a very important question to consider. The Committee had come to the conclusion not to recommend it; and he was bound to say that, even in those parishes which wished a constant supply, there was a very considerable difference of opinion among the inhabitants. Looking at the matter all round, it might fairly be said the Committee had done its duty.

Mr. A. DOUBLE thought this was not the way to treat the Ward of Cripplegate or the City; and he was of opinion that the Committee should have ascertained the wishes of the water consumers of the City before presenting their report. He therefore moved that the consideration of the report should be adjourned, to enable the Committee to obtain the views of the water consumers of the City on the question. He ventured to think that, as London was the wealthiest city of the world, it was simply monstrous that it should be without a constant supply of water. As to the expense of fittings, he wished to point out that a large number of the buildings in the City were of modern construction; and the fittings were in fair condition. Therefore the expense of fittings would be comparatively small. With regard to the willingness of the New River

Company to grant a constant supply to individuals, a short time since he had some correspondence with the Company; and they said, in a letter to him, that, for various reasons, it would not be possible to comply with the wish of individual consumers for a constant service, but that the Company would give careful consideration to any suggestions for supplying a district. There was nothing in the Committee's report or that letter to guarantee a constant supply to any individuals—in fact, he doubted the willingness of the New River Company on this question.

Mr. A. BROOKMAN remarked that St. Giles's was a manufacturing district; and if a constant supply of water were provided, there might be breaks in the pipes and the whole place would be flooded. However, he indorsed Mr. Stapley's remarks that it was a great inconvenience not to have water in the morning. If the matter went before the Committee again, this question might well be considered; and a proposal made to the Water Companies.

Mr. H. CLARKE said the whole question was in a nut-shell. When the Vestries desiring a constant supply obtained a consensus of opinion of the inhabitants of their districts and arrived at the initial cost, then the Court would enable them to get a constant service.

Mr. R. W. SCOBELL asked how the estimate of £300,000 for fittings was arrived at?

Mr. MEAD replied that there were over 30,000 inhabited houses; and in St. Pancras the cost of fittings was £9 a house. Therefore it would be considerably more expensive to put in the new pipes in the City, because of the breaking up of pavements. He estimated that it would be at least £400,000.

Mr. G. N. JOHNSON thought a constant supply should not be forced on any locality.

The amendment to refer the report back found no seconder, and the motion was adopted.

EDINBURGH WATER SUPPLY.

PROPOSED UTILIZATION OF ADDITIONAL SOURCES OF WATER.

At the Meeting of the Edinburgh and District Water Trust held on the 3th inst.—Provost AITKEN presiding—the following memorandum was submitted by the Engineers (Messrs Leslie and Reid), on the subject of a proposal to utilize the Manor Water as a supplementary source of supply for the city and suburbs:—

In view of the probability of an additional supply of water being required at no distant date for Edinburgh, Leith, Portobello, and the districts adjacent, the Water Trustees visited the Manor Valley on the 21st of July last, for the purpose of inspecting the nature of the gathering-ground, and to satisfy themselves as to the suitability of that district for affording an additional supply; and we understand that the Trustees were well satisfied as to the excellence and purity of the water. We therefore think it would not be amiss were we now to present a statement, for the guidance of the Trustees, as to the different schemes which have already been proposed for utilizing the waters of the Manor Valley for the supply of Edinburgh and the surrounding district.

The Manor Water as a source of additional supply was first reported on by Mr. James Leslie in 1870, when he stated that the district "would give for town use and compensation 19,600,000 gallons a day, which, after allowing for compensation, would give 13,000,000 gallons a day for the use of the town. The water seems to be very pure and good; and there is a good site for a reservoir at Posso." The cost of the scheme was estimated at £290,120; and it was further pointed out in the report that the supply available for town use might possibly be increased by forming a reservoir further down the Manor Valley for supplying compensation water to the stream. In 1873 the Mid-Lothian Water Company obtained an Act for bringing in a supply of 5,000,000 gallons per day from the Manor Valley, for the purpose of supplying the county of Mid-Lothian generally, with the power to treat with the Edinburgh and District Water Trustees to supply them with a portion of the water. This Act contemplated the abstraction of the spring water only, and that at a sufficient elevation to avoid the necessity of tunnelling on the line of the pipe-track; and a reservoir was proposed for compensation, to be constructed on the site near Posso, selected by Mr. Leslie in 1870.

In 1874 the Water Trustees, along with the Corporation of Edinburgh, promoted a Bill to obtain additional supplies of water from the Moorfoots; but as the provisions of the Bill to some extent came into conflict with the powers conferred on the Mid-Lothian Water Company, it was considered expedient, in order to avoid their opposition in Parliament, to pay them a sum of £10,000, in consideration of which the Company's powers were allowed to lapse. The fact that Parliament had already granted powers to abstract water from the Manor Valley for the supply of Mid-Lothian, and of Edinburgh, Leith, and Portobello, will no doubt weigh in favour of any future scheme from this source, more especially when it is remembered that the Edinburgh Water Trustees have already supplied to a large extent the very districts which the Mid-Lothian Water Company, intended to provide for in their Act of 1873.

Numerous analyses have from time to time been obtained of the Manor Water; and they all agree as to its purity and suitability for domestic supply. Dr. E. Frankland, Professor of Chemistry in London, in his evidence before the Committees of Parliament in support of the Mid-Lothian Water Bill of 1873, said, as the result of chemical analyses, "I found both samples of the most excellent quality, fit for all domestic purposes, very pure and soft, and free from all suspicion of animal contamination. They were also colourless and palatable;" and, he added: "You could not get a better water supply for domestic use for the supply of a town if you searched the United Kingdom through." There are no manufacturing or other interests on the Manor Water which are likely to offer objections which cannot be met by water compensation in the usual way. It is right to mention that the town of Peebles recently obtained a small supply of water from the Manor by means of a 7-inch pipe; and that, in any scheme for supplying Edinburgh from this source, the interests of the town of Peebles would require to be protected.

For the information of the Trustees, we may mention that the Moorfoot scheme was resolved upon in 1873; and the sanction of Parliament obtained for it in 1874. The estimated available supply from that source is about 9 million gallons per day, which, along with the Pentland water, makes a total available quantity of 16 million gallons per day. The execution of the main portion of the works was completed in 1879; and the Moorfoot water was first introduced in March of that year. At that time the estimated population supplied was about 293,000; while it is now about 378,000. The supplies for trade purposes have also increased from 625,000 gallons to about 2 million gallons per day during that time. The total consumption has risen from 7 million gallons per day in 1879 to 15 millions at the present time; thus leaving a margin of only a million gallons per day to meet the wants of the district until an additional supply be introduced.

Experience has shown that in a district with such inequalities of level as that supplied by the Trustees, and having such large demands for shipping, sanitary, and trade purposes, a constant service cannot be maintained with a consumption of much less than 40 gallons per head per day.

Should the Trustees consider the Manor worthy of further consideration, we would suggest the expediency of having the estimates as to the quantity of water obtainable and the cost of executing the works carefully revised, so as to enable the Trustees, if considered advisable, to make a comparison between this and any other scheme.

Bailie ARCHIBALD, in moving that the memorandum be remitted to the Works Committee for consideration and report, said it appeared to him—and he believed the community were of the same opinion—that it was time the Trustees considered the question of an additional supply of water. They had the fact brought before them in 1879, when the water was first turned on, that they had an estimated available supply of 9 million gallons per day from the Moorfoots. They had used up 8 million gallons of this, and had now a surplus of a million. The total estimated available supply from the Pentlands and Moorfoots was put down at 16 million gallons, of which the Pentlands supplied 7 millions. To show that the Engineers were not over the mark in their estimate, they would see that during the past fortnight the actual supply had been 15,324,000 gallons per day; so that they were coming very close upon their total available supply. If they had any reason to believe that the city of Edinburgh, the town and port of Leith, the burgh of Portobello, and the places that were supplied with water outside this area, were likely to stand still, and that the demand for water would not increase, they might rest perfectly safe with their present quantity. But there was no reason to think that such would be the case; and it was not desirable that it should be so. In looking over the records of the Trust, he found that all the estimates of increasing population and demand for water had been greatly under-stated. An eminent Water Engineer in Scotland, in a report to the Trust in 1870, stated that 20 million gallons, in addition to the supply from the Pentlands of 7 million gallons, would give the increasing population of Edinburgh and district a supply of 50 gallons per head per day for 100 years. Now, 8 million gallons from the Moorfoots had been used in nine or ten years; so that the estimate should now be revised. As to where they should go for a further supply, he did not seek to bind the Trustees; but he had considerable sympathy with the Manor scheme—first, because it was nearer Edinburgh than St. Mary's Loch or the Talla (alternative places); and, secondly, because the water was of undoubted quality and purity. The only other question they had to consider was as to the reasonableness of the price. Mr. Leslie had estimated in 1870 that, allowing 6 million gallons for compensation, 13 million gallons would be available for the town's supply from Posso. If the Manor scheme were treated in the same way as the South Esk, they might, by constructing a compensation reservoir lower down the Manor stream, get from the Posso supply 17 million or nearly 18 million gallons of water per day. They had also to consider that, even supposing they were fortunate enough to pass a Bill during the session of 1889, it would be from six to seven years before the works would be completed and they could get any additional water. If they were now to have two dry seasons, their supply would be short of the demand; and he certainly did not think the present quantity would be adequate for the next seven years. It was clearly their duty, therefore, to take the initial steps to see what they could do to increase the supply.

Mr. COLSTON seconded the motion.

Bailie CRANSTON expressed the opinion that St. Mary's Loch would be a more suitable source of additional supply than the Manor Water. They would get four or five times the quantity from the loch; and therefore he thought it should not be put aside without consideration. Its distance was certainly greater from Edinburgh than the Manor Water; but this could be overcome by an additional expenditure on pipes.

Dean of Guild GOWANS said he knew the Manor district very well; and there was no doubt the water was very pure. They would have to make a new reservoir and new embankments; but possibly they could do this cheaper than by going to St. Mary's Loch. They must not, however, for the sake of cheapness, overlook the advantages of an inexhaustible supply. He would not support the St. Mary's Loch scheme if it were not found to be the best of the projects before them; but they must always remember that they could get as good water there as anywhere else, and that it could be had in unlimited quantities. He proposed a motion recommending the adjournment of the matter for the purpose of allowing the Engineers to report upon other schemes.

Bailie TURNBULL seconded the amendment.

Mr. BROWN asked if the Engineers were perfectly satisfied that they had completely exhausted the Pentlands and the Moorfoots.

Mr. LESLIE replied that these sources were practically exhausted.

Bailie ARCHIBALD said he had made a calculation as to the available supply. They had 16 million gallons from the present sources; 17 million gallons were estimated from the Manor scheme; and as the Manor was the headquarters for St. Mary's Loch and the Talla—and a tunnel could be made to connect these sources—they might add 30 million gallons for St. Mary's, and 22 million gallons for the Talla and the head waters of the Tweed; making a total of 85 million gallons, which would supply a population of 2 million people with 42 gallons per head per day.

Dean of Guild GOWANS then altered his motion to read as follows:—"That it be remitted to the Works Committee, with the aid of the Engineers, to bring up a report on the various available sources of water supply, keeping in view the quantity of water which may be required in after-time, including the Manor, St. Mary's Loch, Talla, and Tweed, and in the case of St. Mary's taking a sample of water down Yarrow."

Bailie Archibald withdrew his motion; and that of the Dean of Guild was unanimously adopted.

BRADFORD CORPORATION WATER SUPPLY.

THE NEW PUMPING STATION AT HEATON.

The new pumping station which the Bradford Corporation commenced about three years ago at Heaton, for the general improvement of the water supply of the district served by the Corporation, by bringing the high and low level systems into connection, is now practically completed. Although the work has only been in progress for the above-mentioned period, the subject had engaged the attention of the Water Committee for something like seven years previous to their decision to commence operations. We give below a few particulars of the new station, which, with the attendant works, has been erected from the plans and specifications of Mr. A. R. Binnie, M. Inst. C.E., the Corporation Water Engineer, with the assistance of Mr. Vaughan, of the Borough Surveyor's office, in the design of the architectural portion of the work. But first of all it may be interesting to give the *raison d'être* of the new station.

Bradford and its suburbs are supplied, as probably some of our readers are aware, with water flowing from gathering-grounds and reservoirs situated at such altitudes as to allow of the water running by the force of its own weight into every house and place where it is required. And because certain parts of the town and surrounding district are much higher than the rest, these have hitherto been served entirely from a separate system—the supply for the lower levels being obtained from tributaries of the Wharfe and Aire; that for the higher levels mainly from the upper waters of the River Worth and the Harden Beck. These systems have

so far been entirely unconnected, and therefore in no way auxiliary one to the other. Inasmuch as the low-level system supplies the central portion of the town, which is most completely covered with buildings, and in which in the nature of things actual increase of population does not go on very rapidly, the growth of the demand upon the sources of supply has not advanced at so rapid a rate as in the higher districts, where the extension of the town and district has been more progressive. The consequence is that the high-level system, which is a much smaller undertaking, is now, relatively to the demand, the less efficient. Thus, while the combined capacity of the low-level works is equal to about 190 days' supply, that of the high-level works is less than 150 days' supply; being a trifle over six months in the one case, and less than five months in the other—amounts which, it may be observed in passing, are seriously below what engineers hold to be a safe minimum for gravitation systems depending upon the fluctuations of rainfall. In the summer of 1884, and again in 1887, it was found to be absolutely necessary to supplement the high-level supply from the resources of the low-level service by temporary pumping apparatus. But as there was no main pipe connecting the two systems, the pumping had to be done through small service-mains only 6 inches in diameter, at a great waste of money for fuel, and with not a little grumbling on the part of those people who resided in the neighbourhood of the four temporary pumping stations. The principal object, therefore, which has been attained by the newly-completed connection may be said to be the strengthening or enlargement of the high-level system by the power of assisting it from the resources of the more extensive and less strained low-level system. But while the connection of the two systems will thus prove of great advantage to the former, it has also a very important bearing upon the position of the latter. The gathering-grounds of the two systems are widely separated, and by no means subject to the same meteorological conditions; and it may happen that an abundant rainfall may fill up the high-level reservoirs, while those on the low-level remain comparatively empty. Such an event is, of course, unlikely; but it occasionally occurs that the high-level system has the heavier rainfall. In such a case the low-level service can be assisted by running water down the main from the high-level service reservoir at Heaton to Heaton, which is the service reservoir for the low-level system. A more important consideration, however, is that this ability to draw upon the high level for the supply of the low gives the inhabitants an element of certainty in their supply which they have not previously felt.

Another purpose effected by the connection of the two systems may be briefly mentioned. The inhabitants of the borough are unanimous now in condemning the principle upon which the high-level system is based. The cost of constructing reservoirs and catchwater conduits at altitudes more than 1000 feet above sea-level, and upon sites not naturally adapted for the purpose, is necessarily very great, and out of all proportion to the advantages obtained; and in any future scheme for the extension of the supply, the water will be collected and stored at more moderate levels, and consequently at a lower proportionate cost. But this means that in the future any enlargement of the high-level supply must be obtained by pumping from the lower level. In this way the Heaton pumping station may be set down as an extension of the high-level service when required to the extent of 2 million gallons a day; or, to put it another way, it practically amounts to an enlargement of the high-level storage equal to 100 days' supply at the present rate of consumption. In determining the scale of the works of connection, regard has been had to all the foregoing considerations.

The pumping-engines which have been fitted up are only an instalment of the entire system. Although the pumping main is equal to conveying 4 million gallons of water per diem from Heaton to Heaton, it was not necessary to put up engines of this capacity just yet; and therefore those which have been erected, and which are in duplicate, are designed to lift 1 million gallons each per working day. They are of the Worthington type, and have been built by Messrs. James Simpson and Co., Limited, of Pimlico, who have supplied similar engines to several of the London Water Companies, as well as to water-works in all parts of Europe. One set of these engines, recently built by the firm for the West Middlesex Water Company, lift 2½ million gallons of water in 24 hours, or 2½ times the whole consumption of Bradford. The engines are compound, direct-acting, and have no rotary parts. Each engine has two high pressure and two low-pressure steam cylinders, arranged tandem fashion, and two double-acting pumps. The diameter of the high-pressure cylinders is 20 inches; of the low-pressure ones, 40 inches; of the pump-rams, 11 inches; the length of the stroke being in every case 2ft. 6in. The engines are provided with an ingenious arrangement of double plungers, which have the effect of greatly steadying the stroke. Power is derived from two three-flued Lancashire boilers, 30 feet in length and 8 feet in diameter; and the flues are two of them 3 feet, and one 2ft. 6in. diameter. To the bridge at the rear of the fire-grate they are fitted with Fox's corrugated flues. The engine-house is a substantial and not inelegant structure of stone, 41ft. 6in. by 35 feet internal area. It is flanked by the boiler-house, 50 feet by 40 feet, and by a mechanics' shop and a coal-house, each 23 feet square. The boiler-house is large enough to contain a third boiler of the same dimensions as those already fixed. What may be described as the basement of the engine-house is well lighted from an area extending round three sides, the walls of which are faced with white tiles. The chimney is 180 feet high; the main part of the shaft being octagonal. The contract for the engines was £5282; that for the buildings, £5186.

WOODEN WATER-MAINS.

[From the *Standard*.]

The exhumation not long ago of sundry wooden tubes or pipes in front of the new Law Courts in the Strand, has drawn attention to some of the bygone conditions of the water supply of the Metropolis. That wooden water-pipes were also used in the provinces in past years is well known; and the records of the Hertford Corporation contain sundry entries of money paid for the construction and repair of such pipes during the sixteenth century. To lay down a cast-iron main for the conveyance of water would seem a very simple and obvious contrivance. Yet the history of the water supply shows that it has required a long course of experience to bring the mode of distribution to its present point of refinement. There has been the leaden age, the wooden age, for a brief period the stone age, and now at last the age of iron.

It seems like a curious anticipation of the present schemes of Local Government and the possession of the Metropolitan Water Supply by a municipal authority, that quite at the commencement of the thirteenth century the Corporation of London intercepted certain springs feeding the watercourse known as the Tye Bourne, and gathered them into reservoirs situated near Marylebone Lane. From this point the water was conducted in a 6-inch lead pipe to Charing Cross, along the Strand and Fleet Street; crossing the Fleet by means of the bridge which then existed at that spot, and proceeding up Ludgate Hill to Cheap-side, where it was discharged into the conduit at the western end of that thoroughfare. This water was derived from the gravel beds forming the subsoil of Marylebone; and in those days was doubtless free

from any dangerous contamination. The degree of hardness attaching to it would also prevent any risk of lead poisoning. At the present time a portion of the water supply of the Metropolis is drawn from the gravel beds which underlie the banks of the Thames above London; and the Water Companies are endeavouring to increase the quantity taken from this source. These Marylebone Water-Works—if we may so term them—were the property of the Corporation; the owner of the land whence the springs issued being induced, under Royal influence, to make a grant of the water to the civic authority. The lead pipe was paid for by certain merchants of Ghent, Bruges, and Antwerp, who received as a *quid pro quo* an exemption for a term of years from river dues and tolls on the goods they imported into London. The King took his share of the benefit by having a gratuitous supply of water for his stables, situated on what is now the north-east corner of Trafalgar square. For many years the Corporation paid an annual visit of inspection to the Marylebone springs and reservoirs; celebrating the event by a dinner held in a banqueting hall constructed on the arches by which the reservoirs were covered.

The supply of water to the people of London by means of conduits, utilizing local springs, proved insufficient as the Metropolis grew in size. Traces of this obsolete method are preserved in the names of Conduit Street, Lamb's Conduit Street, and Conduit Vale. Towards the close of the sixteenth century, recourse was had to the Thames; and as the main drainage works were then altogether out of the reckoning, the river at London Bridge was deemed a source sufficiently pure for a domestic water supply. This was the beginning of a new order of things, and brought with it what may be called the age of wood. An enterprising Dutchman, named Peter Morrys, having obtained the consent of the Corporation, erected a tidal water-wheel under one of the arches of Old London Bridge, by means of which he worked a force-pump, raising water from the Thames, and driving it through leaden or wooden pipes laid in the streets, whence branch-pipes conveyed water into the houses. This was fairly the germ of the system which now governs the Metropolitan Water Supply. The tidal wheels under London Bridge were increased in number to meet the growing demand, until at last, in 1820, the works at the bridge supplied as much as 26 million hogsheads of water during the year. As the London Bridge water-works came into operation soon after 1582, it is possible that wooden pipes 300 years old are to be found in some parts of the City. But although the supply went as far west as Fleet Street, it is not certain that the Dutchman's wooden pipes extended beyond Temple Bar. When the London Bridge water-works were discontinued, consequent on the pulling down of the old bridge, the New River Company made an equitable arrangement with the proprietors, and absorbed the Dutchman's arrangement into their own. The area served by the New River Company extends along Fleet Street into the Strand; and wooden pipes have been dug up in Fleet Street, apparently continuous with those opposite the new Law Courts.

It was not long after Peter Morrys set up his water-wheels that the New River project was started, in some degree introducing a competing supply. It was a great achievement to bring the pure spring waters from the neighbourhood of Ware, in Hertfordshire, into the reservoirs at Clerkenwell; but it was also felt to be a difficult matter to distribute the water to the various parts of the Metropolis where it was needed. "This was done," says the record of the time, "with all possible diligence, by pipes of elm and lead, but for the most part elm, from which pipes many high streets and lanes within the City are plentifully served." This plentiful serving is exemplified by the circumstance that in 1616, in consideration of a certain sum to be paid yearly, Sir Hugh Myddleton granted to a citizen and his wife a lease for 21 years "of a pipe or quill of $\frac{3}{4}$ -inch bore, for the service of their yard and kitchen by means of two swan-necked cocks." Such a supply as could be obtained through a pipe "of the size of a goose-quill" was that which the King obtained from the Corporation in recognition of the Royal assistance in getting a grant of the water at Marylebone. Perhaps the supply was constant, in which case it would excel the present intermittent system; and, when the water flows continuously, a goose-quill will yield a considerable quantity. In the foregoing lease granted by Hugh Myddleton, the "quill" is specified as being $\frac{3}{4}$ inch in diameter, which shows that the term had a technical meaning when not otherwise expressed.

Some singular relics of the old water supply of London were shown in the International Health Exhibition, at South Kensington, in 1884. The New River Company sent a pail made out of an old wooden pipe dug up in Southampton Row, as also one of the actual pipes. The East London Company threw some light on the manufacture by exhibiting a set of cutters used in boring the wooden mains. These tools were said to be about 100 years old. The Grand Junction Company sent a specimen of a wooden water-main "as formerly in use in the London streets," dug up about seven years previously. The Southwark and Vauxhall Company exhibited some old wooden pipes and stop-valves taken out of the ground in Redcross Street, Southwark, and supposed to have been fixed about the year 1814—a somewhat late period. The West Middlesex Company sent specimens of stone pipes, "as used by the Company until 1807 for supplying the water into the district." The same Company also furnished specimens of the wooden pipes. They abandoned both stone and wood in 1807. Stone was tried as a substitute for wood, in the hope that it would prove less liable to leak. It probably proved the worse of the two, owing to the yielding of the joints under pressure. The West Middlesex Company appear to have entertained considerable hope at one time that stone pipes would answer, judging by the fact that they laid down a quantity in various parts of their district, the diameters ranging from 2 to 12 inches. The Hertford records show that wooden pipes were sometimes strengthened by means of iron hoops. Elm was used at Hertford, as in London; and the process of boring is mentioned. The date of 1814, when the Hertford Corporation resolved on using iron pipes instead of wooden ones, corresponds very closely to the time when the same change took place in London. The necessity of having mains of large diameter, and the general requirement for water at high pressure, would help to render wood an obsolete material. The East London Company laid iron pipes at the commencement of the present century, in lieu of the old wooden ones of the Shadwell and West Ham Companies; the complaint being that the wooden mains "were totally inadequate to withstand the pressure." But the cost of substituting iron for wooden pipes, together with the erection of some powerful pumping machinery, was felt as a heavy burden by the Southwark and Vauxhall Company about half a century ago.

INCORPORATION OF CHELMSFORD.—A movement was set on foot some months ago to obtain a Charter of Incorporation for the town of Chelmsford; and although it was opposed by many of the largest ratepayers, an overwhelming majority of the inhabitant householders was in its favour. In February last the Hon. T. H. W. Pelham held a three days' inquiry into the matter; and on the 15th ult. Mr. Furbank, the chief promoter of the project, received a communication from the Privy Council that the Queen had been pleased to grant the Charter. The event was celebrated in the borough last Wednesday in an enthusiastic manner.

NOTES FROM SCOTLAND.

(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.

The Edinburgh and Leith Water Commissioners are earning "golden opinions" on account of their continued reduction of the water-rate. This is the second year in which they have relieved their ratepayers of a half-penny in the pound. This is not done with a view to "cook" the accounts of the Trust before going in for a scheme of extension. Mr. Colston made that clear in his speech yesterday, in moving the adoption of the report. The statement submitted by Mr. Oliver, the Interim Treasurer, showed that for 1888-9 the estimated expenditure was £82,304, and that with a domestic rate of 6½d. per £, a shop rate of 2d. per £, and a public rate of 1d. per £, the receipts would be £82,776. In 1887-8 the estimated expenditure was £82,622; and the amount actually spent was £81,827. The estimated receipts for the year from a domestic rate of 7d. per £ and a shop and public rate of 2d. and 1d. in the £ respectively were £84,510; but the actual receipts amounted to £87,925—thus showing that the receipts for last year exceeded the estimated amount by nearly £3,000, while the actual expenditure was less than the amount obtained from assessments by more than £600.

A proposal having been made that the local gas-works should be taken over by the Corporation of St. Andrews, a correspondent writes to a newspaper calling attention to the cost of gas in 18 Scotch towns of about the same size as St. Andrews. Of these, 5 towns already own the gas-works; and 13 are supplied by Companies. It is interesting, in view of the generally prevalent belief that Corporations supply gas at a cheaper rate than Companies, to find that, in nearly all the instances given, the cost in the case of Corporations is higher than in that of Companies. In the 13 towns supplied by Companies, the average price of gas is 4s. 4½d. per 1000 cubic feet; and in the 5 towns supplied by Corporations, the average price is 4s 8½d.

The Arbroath Gas Corporation had a somewhat excited meeting on Thursday over Mr. Michie's proposal to rescind their former resolution to immediately go on with the extension of the gas-works.* A majority has resolved to carry out the work; but they do not appear to know their own mind, and it is understood that no progress is to be made until after the municipal elections.

On Thursday, in the Bill Chamber of the Court of Session, Lord Fraser had before him a case in which Messrs. S. Clark and Co., Stove Manufacturers, of Park Street, Islington, asked that Mr. W. Bruce Dick, carrying on business under the name of the London Fire Appliance Company, in Buchanan Street, Glasgow, should be interdicted from infringing letters patent, dated Sept. 19, 1881, granted to the complainant for improvements in gas and oil stoves, or apparatus for heating and lighting purposes. In support of the application it was said that the invention had been found to be very useful; and that the stoves manufactured by the complainant to which it had been applied had found a large and ready sale. Until recently they were doing a good business; and they averred that the proceedings complained of had seriously checked their sale and injured their business. They alleged that the respondent was manufacturing and selling in his own name or that of the London Fire Appliance Company, of which he is sole partner, gas and oil stoves, in the construction of which the said patented inventions are used without their authority or licence, and was thus infringing their patent rights. The respondent resisted the application on the ground that the complainant's averments are irrelevant and wanting in specification, and that the letters patent are invalid in respect that the alleged invention, or a material part thereof, is not competently the subject-matter of the grant of letters patent; that the specification does not sufficiently distinguish between what is new and what is old in the invention; that the complainant is not the first and true inventor; and that the invention was publicly known and used prior to the date of his letters patent. He says that the stoves were extensively made and sold by several firms in London and Warrington, and that the complainant Clark was for some time Manager of one of these companies. After debate, Counsel agreed that the respondent should lodge a minute undertaking to keep an account of all sales of the articles in dispute; and in respect of this minute, the Lord Ordinary, upon caution being found by the respondent for all profits arising out of the sales, refused interim interdict, and, as regards the complainant, passed the note without caution.

The Stirling Water Commission on Tuesday were able to announce a reduction of the water-rate by 3d. per £; making a decrease of 6d. per £ within two years.

The Bervie Gas Company have reduced the price of gas 5d. per 1000 cubic feet; making it 8s. 9d., which is still a very high figure.

The Bo'ness Gas Company have contracted with the Police Commissioners to supply gas for the public lamps on 218 nights in the year at the rate of 16s. each for lamps burning to eleven p.m. during the week and twelve p.m. on Saturday nights, and 28s. each for lamps burning all night. This is a reduction of about 1s. 6d. per lamp.

The Keith Gas Company, it is reported, have recently made considerable improvements in their works, and have reduced the price of gas from 7s. 1d. to 6s. 8d. per 1000 cubic feet.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.

At a meeting of the Gourrock Burgh Commissioners on Tuesday, it was resolved to reduce the price of gas to private consumers 2½d. per 1000 cubic feet—that is to say, from 4s. 7d. to 4s. 4½d.; and it was at the same time agreed to increase the charge for gas supplied to the public lamps by 3½d. per 1000 feet—from 4s. 1d. to 4s. 4½d.; so that henceforth the price in both cases will be the same. During the year 1874-5 the price to private consumers was 5s. 10d., and for the public lamps 4s. 6d. per 1000 feet. A reduction of 5d. per 1000 feet was made on June 1, 1876, to ordinary consumers; but the charge for public lamps remained unchanged. At the close of the year another reduction of 5d. was conceded to the private consumers; the price being thus brought down to 5s. per 1000 feet—that for the gas consumed in the public lamps still remaining at 4s. 6d. per 1000 feet. These two prices were continued till May, 1882, when 5d. per 1000 cubic feet was taken off in each case; the prices being 4s. 7d. and 4s. 1d. respectively. No further alteration was made in the charges till the reduction in the one case and the increase in the other were made at the last meeting of the Police Commissioners—not even when the gas supply of the town was taken over by the Commissioners on May 31, 1886.

It may be mentioned that Mr. D. M. Nelson, Gas Engineer, of Glasgow, has just been appointed by an eminent firm of foreign merchants to superintend the execution of a very extensive cast-iron pipe contract—no less, it is said, than 200,000 yards of pipes—for gas supply abroad.

The shares of the Partick, Hillhead, and Maryhill Gas Company have this week again been in demand. Business was done in them on the Glasgow Stock Exchange yesterday at 88s. 6d. per £5 share. Mention of this circumstance leads me to state that no further progress has been made with the negotiations for the acquisition of the Company's property on behalf of the Glasgow Corporation Gas Trust. It is but fair to say,

* A report of the discussion is given on p. 556.

however, that the negotiations up to the present have been conducted wholly on the authority of the Gas Committee, and without the official knowledge of the Gas Commissioners generally. The matter is now in the "simmering" stage.

At last Monday's meeting of the Glasgow Town Council, sitting as the Police Authority, there were submitted the minutes of the Watching and Lighting Committee, in which it was recommended that the salary of Mr. Hamilton, Inspector of Lighting, should be increased from £300 to £350 per annum. Ex-Bailie Dickson moved the approval of the minutes, and asked that the Standing Orders should be suspended, so that the recommendation might be agreed to. Mr. Paton said that he did not object to the increase of Mr. Hamilton's salary, but he thought that the usual practice adopted in such cases, of allowing the recommendation to stand over for a fortnight should be followed on this occasion. Bailie McFarlane interposed the Standing Orders. Bailie Gray, who presided (in the absence of the Lord Provost), pointed out that as the Standing Orders had been interposed, the recommendation to increase the salary must stand over till the next fortnightly meeting. It is not anticipated that there will be any difficulty in getting the proposal carried, as it is very generally admitted that Mr. Hamilton has been a most useful, zealous, and efficient public servant. Any person who remembers what the public street lighting was (say) ten or a dozen years ago, and can compare it with the present condition of things, will agree with me in what I have said of the Inspector of Lighting.

The half-yearly meeting of the Dalnair and Old Kilpatrick Gas Company was held last Saturday, when the Directors reported that, after meeting all expenses, they were able to recommend that a dividend of 5 per cent. be declared. The recommendation was agreed to. It is intended to reduce the price of gas 5d. per 1000 cubic feet.

Many readers of these "Notes" will doubtless learn with regret and surprise of the sudden death of Mr. James Boyd, the Manager of the Oban Gas-Works, which took place at his residence last Tuesday morning. After breakfast he was noticed by his daughter to fall back in his chair; his death being almost instantaneous. Dr. McKelvie, who was at once summoned, certified the cause of death to be heart disease. Though slightly ailing for some time, Mr. Boyd had been able to attend to his duties; and the news of his death came upon his numerous friends and acquaintances as a shock. The deceased had been the Manager of the Oban Gas-Works for the long period of 21 years. Being of a most kindly and genial disposition, he made firm friends of all persons with whom he was brought into intimate contact; and his loss will be widely felt. He has left two daughters, for whom much sympathy is expressed.

Prices in the Glasgow pig iron market have fluctuated very much during this week; but the tone has been decidedly firm throughout. In the beginning of the week the market was strong; business being done on Tuesday at 42s. 10³/₄d. per ton for Scotch warrants—the highest price for the past six months; but during the rest of the week the price was irregular, owing partly to operators taking profits and to "bearing." On the following day the price touched 42s. per ton cash; and the close yesterday was 42s. 2d. per ton cash sellers. The price of hematite iron fluctuated during the week between 46s. and 45s. 3³/₄d. per ton, and that of Cleveland iron between 35s. 1d. and 34s. 7d.; both being somewhat better at the close yesterday afternoon.

The coal trade continues active in all its departments; and the improved feeling in the trade is stimulating production in several directions. Prices are firming up; and an advance of 1s. per ton is expected on house coal within the next week or two.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Sept. 22.

Sulphate of Ammonia.—Business was done at the beginning of the week at £11 6s. 3d., f.o.b. Hull; but, in consequence of a good French inquiry, £11 7s. 6d. has since been readily paid for spot parcels, and at the close there are still buyers thereat. It is evident that the fine harvest weather has cheered the spirits of consumers; and that the orders, at any rate as far as France is concerned, have come in more freely than was expected. The present demand, however, will hardly make up for the shortcomings in respect to the exports to that country during this year. Germany and Belgium, most strangely do not appear to move much as regards present delivery; but, on the other hand, the inquiries from these countries for spring delivery are active. Little business passing, however, owing to the difference between the buyers and sellers. It is difficult to gauge the market at present; but should the present bright weather continue to prevail, it will retard the increase of the liquor supply which usually occurs on the approach of October.

LONDON, Sept. 22.

Tar Products are in better demand, and firm in price. There is no great activity in benzols; but last week's prices are maintained. Anthracene, creosote, and pitch are all in good request, at improving prices. Prices may be taken as follows:—Tar, according to position, 17s. 6d. to 22s. 6d. per ton. Benzol, 90 per cent., 8s. per gallon; 50 per cent., 2s. 4³/₄d. Toluol, 1s. 9d. per gallon. Solvent naphtha, 1s. 2d. per gallon. Crude naphtha, 30 per cent., 1s. per gallon. Light oil, 3d. per gallon. Creosote, 2d. per gallon. Pitch, 12s. to 13s. 6d. per ton. Carbolic acid (crude), 3s. 4d. per gallon. Cresylic acid, 9d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 6d. per unit; "B" quality, 1s. 3d. per unit.

Ammonia Products.—Sulphate is recovering from the lower prices of a few days ago, and is quoted at £11 7s. 6d. to £11 10s., less discount. Other products are as follows:—Gas liquor (5° Twaddell), 7s. 6d. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 1¹/₂d. per lb. Carbonate of ammonia, 3³/₄d. per lb. Muriate of ammonia, brown, £18 per ton; white, £27. Sal-ammoniac, £30 per ton.

[From the Chemical Trade Journal, Sept. 22.]

Sulphate of Ammonia.—The market is very dull; and dealers appear to be the only buyers at the moment. It is, however, rumoured that Hull business has been done at £11 6s. 3d. for prompt, which buyers are willing to pay; and there are several sellers at this price. There is a very large inquiry for spring delivery, which bodes well for the future, but makers decline to sell far ahead at the present prices, and even speculators do not seem inclined to commit themselves to any large transactions. Loth and Beekton prices may be taken as £11 5s.; while outside London makes are value for £11 8s. 9d.

Tar Products.—Benzols remain without change; and the prices quoted for last week—viz., 2s. 10d. to 3s. for 90's and 2s. 4d. for 50.90's—may be taken as about the figure for to-day. The demand still continues good for solvent naphtha at old rates; while creosote is, if anything, a shade firmer than before. Anthracene is still firm at 1s. 6d. for "A" quality, London; the value for "B" being as before, 1s. 2d. There is a very fair demand for pitch; and some considerable quantity of accumulated stocks has been moved off during the last month or so. With the single exception of benzol, which is, in spite of the maintenance of price, in an unhealthy state, the tar products market may be said to be in a satisfactory position; and so long as benzol prices are artificially inflated,

distillers may reckon on a fair margin of profit, even on the basis upon which many recent tar contracts have been secured.

SALE OF SHARES IN THE UXBRIDGE GAS COMPANY.—Last Thursday: Messrs. Morten and Sons sold by auction, at Uxbridge, a number of £10 shares in the Uxbridge and Hillingdon Gas Company. The sale included 21 original shares, paying 10 per cent. per annum; 9 of the 1861 shares, paying 7¹/₂ per cent.; and 19 of the shares of 1873, paying 7 per cent. The biddings for the last began at £10, and the first lot of two shares was sold at £12 10s. each; but others fetched as much as £13 15s., £14, and £14 5s. The shares of 1861 fetched from £14 10s. to £14 15s.; and the original shares went at £13 10s. each.

LAUNCESTON (TASMANIA) GAS COMPANY.—The Directors of this Company report that the business in the half year ending June 30 last made satisfactory progress. New consumers were supplied, and the use of gas was extended. In order to keep pace with the increasing demand, mains of larger size were put down in various parts of the town, whereby the supply was greatly improved. The coal and cannel carbonized during the six months covered by the report amounted to 2244 tons; the quantity of gas produced being 24 million cubic feet. The Directors recommended a dividend at the rate of 12 per cent. per annum, and this was declared; an interim payment of 5¹/₂ per cent. having been made in February last. The amount now standing to the credit of the profit and loss account is £3449 16s. The Directors announce a further reduction in the price of gas, from June 1 next, to 7s. 1d. per 1000 cubic feet. The Company's Engineer is Mr. T. S. Clemenshaw.

NORTHERN COAL TRADE.—In the steam coal branch of the Northern coal trade there is still a fair amount of business; but the prices continue low—about 7s. 6d. for best Northumbrian qualities. The demand shows some signs of flagging; but it will possibly flicker up again before the closing of the Baltic ports. In the gas coal trade there is great animation; and the tendency of some of the miners to restrict the output will increase the scarcity which is beginning to be felt for this class of coal. Tenders are asked for the supply for the Darlington Gas-Works; and it is expected that higher prices will have to be paid than on the last occasion. There is still a large demand for gas coal for export; and the growth of the British demand is now felt every week regularly. The price of gas coals is maintained. Manufacturing coal is also much dearer—possibly about 6d. per ton; and the activity at many of the factories causes a growing inquiry for this class of coal. Household coal is depressed by the finer weather. Coke is brisk, and sells at higher figures.

THE JOURNAL OF GAS LIGHTING, WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, OCTOBER 2, 1888.

OIL-GAS FUEL SCHEMES.

If another confirmation were wanted, the truth that history repeats itself would be enforced by what is at present passing in respect of the revival of interest in oil-gas processes. For some years, while electricians were "making ducks and drakes" of other people's money, all kinds of illuminating and heating gases were popularly supposed to be on the verge of extinction. Now however, the tide has turned; and when one takes up a technical periodical published in the land of Edison, Brush, and Westinghouse, where the rashest speculation in manufacturing methods seems to rule triumphant, it is not a new electric lighting, but a novel gas-making scheme that calls weekly for favourable notice. In the ordinary way we are compelled to take account of the contents of the leading American engineering journals, in order to learn what is going on in the country whence the historical electric light "scare" was imported; and it is a striking fact that for some time past these publications have had little to say about electric lighting, but have been filled with descriptions of oil-gas schemes. The reason is obvious. Natural gas, while still maintaining its position in Pittsburgh and other places, has done its pioneering work. The natural gasiform fuel, which was once a wonder of the world, has been tamed and brought into the service of mankind. No longer

roaring aloud to heaven without purpose, as it issued tumultuously and uselessly as a volcanic eruption from the well sunk in vain search for oil or brine, flinging its flames aimlessly down the wind, a wonder to gaping witnesses, natural gas has been captured and enclosed in pipes. At first almost given away to anybody who would undertake to show how it might be utilized in place of solid fuel, natural gas has now found its value, like every other useful thing in the world; and the dreams of manufacturers who thought to obtain fuel in this shape for nothing have been rudely broken. Natural gas must now be paid for at rates approximating to its fuel value as compared with coal. The consequence of the long experiments that have been made with it, however, while it could be had for the asking, in connection with a variety of manufactures, is that artificers who have once grown used to it do not relish the idea of returning to coal. The raising of rates for natural gas in some localities, and the indications in others that this remarkable production of natural forces is not likely to prove permanently available, have inspired engineers with a desire to discover a substitute for it. Hence the popularity of oil-gas fuel schemes, not one of which would have been looked at a second time if natural gas had not prepared the field for them. The wastefulness with which natural gas was at first used in the arts, and for domestic purposes, was a preparation for the more economical methods required for dealing with a manufactured fuel of the same order. If natural gas had always been dear and scarce, or if even the most moderate degree of care in the use of it had been essential for its success as a fuel, it would not have ousted coal from its traditional place. Apparently as free and boundless as sunshine, however, natural gas conquered all prejudice against such a strange form of fuel, and won its way with the most obstinate puddlers, glass melters, and steam users of its native region. This stage was necessary. If any British Gas Company could afford to promise the inhabitants of their district a free and unrestricted supply of gas for lighting, heating, and developing power for a year, they would be able to secure a greatly increased rental for the following year; because gas, once adopted, would in very many cases be retained. So it has been with natural gas. By the very prodigality of its occurrence it won favour, which has been retained in spite of the return of economical considerations.

Therefore, the transition from natural gas to be had for nothing to natural gas that must be paid for at its comparative fuel value, is not more reasonable than the appearance of manufactured fuel gases of various descriptions to compete with the natural fuel in its latter days. As one of the American technical journals puts it: "Manufacturers have so fully appreciated the value of a gaseous fuel, that a recurrence to coal is 'out of the question—it is now a choice of gases.'" Consequently, a variety of gas-making processes, naturally enough depending upon crude petroleum as the raw material, are coming forward on all sides; and nobody seems to reflect that not one of them is entitled to be called new. It is as though the novelty of the demand for something of the kind covered the supply. This ignorance of what has been done in their own country in the way of producing gas from oil is only what might be expected of the writers in the ordinary American newspapers; but we have looked in vain for any trustworthy statement upon the subject from experts worthy of respect. Week by week gas-making processes, dubbed by strange proprietary titles, are described and warmly recommended by newspaper writers, who assure their readers that every one in turn is the solution of the problem that everybody has been looking for; and nobody attempts to instruct the public concerning the rights of the subject. There is never anything new in these devices. They all rest upon the gasification of petroleum in tubular retorts, and the dilution of the products with heated steam or air, or both—a notion as old as the hills. We take the contents of a single advertisement page of the *American Manufacturer*, and herein we find no less than five oil-gas processes offered to the bewildered inquirer. There is the "Brooks" process, recommended to Gas Companies for competition with electric light, and to manufacturers as a substitute for natural gas. Then there is the "Eureka" process, the name of which is almost enough to condemn it, but which is stated to be cheaper than natural gas. Next comes the "Loomis" process, claimed to be the "cheapest" gas-generating system in the world." This is a generator system, using coal however; and it therefore scarcely comes within our present notice. The "Naysmith" process is an example very much to the point; the gas being advertised as

"made from oil, steam, and air, and costs less than natural gas." Last comes the North-West Gas Improvement Company, licensees of Dr. J. J. Johnston's process of manufacturing gas from crude oil at "less than the ordinary cost of natural gas. Illuminating gas at 4 cents per 1000 cubic feet." We take the occasion for declaring that there is nothing in any of these advertised oil-gas processes that they should be distinguished by any man's name. A small iron retort, a barrel of oil, a furnace, and the necessary pipe connections, are all that is needed to make gas as good as can be produced by the best of them; and the gas when manufactured can be diluted to taste with steam or air. There is nothing proprietary in all this. Neither is there any limit to the bulk of "gas" that can be made from a given quantity of oil and steam or air, on the homœopathic principle that the more the dose is diluted the more effective will it become. The only possible difference there is between the new oil fuel gases that are recommended as substitutes for natural gas and the illuminating oil gases that were tried and abandoned years ago is the very small one that the former are more diluted than the latter. Are they really worth anything, however? That is the question for the public. We answer roundly in the negative. The various patterns of apparatus, by whatsoever name known, are only calculated to deceive purchasers at first, and to be consigned to the waste heap after a short and troublesome existence.

It is very easy to support this statement with reasons well known to everyone who has essayed the delusive experiment of making gas from petroleum in closed retorts. Half of the raw material is deposited in the form of carbon on the interior surfaces of the retorts, where it acts as a non-conductor of heat; clogging the retorts and preventing gasification even while the outside temperature is increased to the melting point of the iron. Frequent cleaning is necessary, or gas making cannot be continued. Then it is impossible to continuously superheat steam—to the point, that is to say, when it will not condense again—in closed iron pipes. The metal quickly oxidizes, or the steam passes unaffected. As to the utility of introducing air into the gas, while in course of production, it is no more competent to form gas than it is if mixed with the hydrocarbons in an atmospheric burner at the point of ignition. The only means by which steam and air can be made instrumental in producing a real gas is in open converters such as are employed in water-gas processes. Everything else, in the character of retort, superheater, or what not, is a delusion. If natural gas is to be replaced by a manufactured gaseous fuel, this must be made in generators or producers, resembling nothing which enters into the scheme of the crude oil processes under examination.

We have been thus particular in exposing the futility of these oil-gas schemes, not wholly in the interest of the American manufacturers to whom they are in the first place addressed, and who are not likely to be deceived by them to any notable extent, although strongly recommended by their own technical organs. It is quite possible, however, that, like "Lawrence" gas and other similar revivals of exploded delusions, a few of them may cross the Atlantic, and receive the *imprimatur* of some of those lights of English science who are always open to sell certificates of character for any scheme that is sufficiently strongly supported in the City. We notice the rise of this movement in favour of oil gas for fuel in order that, if such development should be in store for it, our readers may not be taken by surprise.

THE ACCOUNTS OF THE COMMERCIAL GAS COMPANY.

The report of the Directors and the statement of accounts of the Commercial Gas Company for the six months ended June 30 last have been issued, in view of the half-yearly general meeting which is to be held next Friday. Before dealing with the matter of the report and accounts, we may be permitted to express the satisfaction with which we notice that they are still signed by Mr. R. Bradshaw, as Chairman; and we hope that Mr. Bradshaw's health is sufficiently restored to enable him to assume the chair as usual at the meeting. The report is the baldest statement of the chief figures of the accounts. It recites that there has been a net profit of £52,166 on the half-year's working of the undertaking; making, with £1044 received for interest, a gross sum of £53,210, which the undivided balance brought forward swells to £97,293, as the amount from which the dividend and other charges may be taken. Deducting interest on debenture stock, there remains a balance of £94,565, of which £44,800 is available for division. The handsome dividends

already announced, of £13 15s. per cent. upon the old, and £10 15s. per cent. upon the new stock of the Company, are then recommended. The report says absolutely nothing respecting the condition of the Company's business; and one is left to find out whether the consumption of gas in the district, or any other of the circumstances of the undertaking, show improvement, stagnation, or decline. Twelve months ago the accounts for the corresponding period of 1887 showed a net profit of £43,008; so that there has been a great improvement in this respect—the price of gas having been the same. In the present accounts, gas-rental stands at £116,947, as against £112,176 a year ago. Residuals also are returned at £37,523, as compared with £34,533. The gross revenue, therefore, shows an improvement of £7755. On the other side of the account, coals have cost £57,694, as against £59,009, which is very satisfactory economy. The manufacture of gas altogether cost the Company £85,972, instead of £87,496. Distribution is a little more, but some of the other charges show a slight diminution; so that altogether the expenditure has been reduced from £106,545 to £105,141. For this, 96,080 tons of coals were carbonized, including 3426 tons of cannel; as compared with 95,063 tons of coals, including 3638 tons of cannel, for the first half of 1887. The cannel shows a slight decrease, but we cannot help thinking that there is still plenty of room for improvement in this respect. The gas sold amounted to 918,668,000 cubic feet, or an increase of 4.53 per cent., which cannot but be regarded as remarkably good. It is a long time since the Company had so large an increase; and we trust it is a good sign both for the future of the undertaking and the prosperity of that part of London in which its business lies. Meteorological influences may have had something to do with the sudden expansion of the consumption of gas within the Company's district, which we have on a previous occasion described as being within a ring fence. After all has been said upon this score, however, it remains open to remark that trade in the East-end of London cannot be in a very bad way when the consumption of gas shows this strong growth. From all this it will be seen that the proprietors of the Commercial Company have every reason to be satisfied with the condition and prospects of their property; and they will be able to pass the high rate of dividend recommended by the Board with the comfortable feeling that it has been well earned.

THE EASTERN COUNTIES GAS MANAGERS' ASSOCIATION.

An Eastern Counties Association of Gas Managers was founded last Wednesday at Peterborough; thus crowning with a well-deserved success the public-spirited endeavours of Mr. Wimbhurst, of Sleaford, who, with Mr. J. Barton, of Peterborough, and Mr. J. Carter, of Lincoln, undertook and performed with much address the troublesome preliminary work required for the establishment of such an organization. Mr. Wimbhurst and his colleagues issued a circular-letter to gas managers resident in the district to be covered by the proposed Association; and although they only received 24 entirely favourable replies, they decided—and it is to be hoped wisely—that this was a sufficient basis upon which to start the society. It is, of course, impossible to forecast the career of the institution which was created in such a hopeful spirit last week; but we are at least free to assert that its beginnings have been as promising as the most sanguine of founders could desire. Mr. Barton, in the remarks (reported elsewhere) which he made respecting the desirability of an Association for the district, struck the right chord; and he was well supported by Mr. Wimbhurst, who formally moved, in singularly frank and appropriate terms, the resolution in favour of founding such an Association. The rules of the new body are closely modelled upon those of the Midland Association; and, by what may be regarded as the fundamental law of its existence, it is enacted that "the Association shall consist of 'Engineers, Managers, or Secretaries exclusively engaged 'upon gas-works, in the service of Gas Companies or Local 'Authorities.'" Thus there is to be only one order of members, and from this traders—and, in short, all the outside world, as the Secretary put it—are to be excluded. The style in which the formal work of passing rules and choosing the first office-bearers was performed, augurs well for the future of the Association. Mr. W. Barratt, of Grantham, was elected first President; and there can be no doubt that the choice is a thoroughly judicious one. It will not be Mr. Barratt's fault if the roll of members is not greatly lengthened before he quits the chair. The first ordinary meeting is to be held on the third Wednesday in March next, at Grantham; and thenceforward there will be

two meetings a year, in March and September. It is wise not to overburden the young organization with too frequent meetings, especially as the towns from which its members hail are scattered over a wide expanse of country, and each gathering will mean practically a day's work for the majority. It is gratifying to know that the suggestion on the vexed subject of papers for these District Association meetings, which we offered in last week's JOURNAL, has been well received by some of the founders of the new society. It is to be hoped, of course, that the Secretary will be able to obtain a fair supply of papers for some at least of the meetings; but it is very certain that it would be found a mistake to rely so exclusively upon formal papers that the occasional paucity of this kind of attraction to the meetings could be regarded as depriving them of all interest. We wish the new Association all possible success, and trust it may prove an influence for good in the district over which that influence will extend.

AFFAIRS AT HALIFAX.

MATTERS at Halifax seem to be ripening, and by this time next week the local public ought to be in possession of something definite in connection with the so-called "scandal" that has vaguely excited them for the past three months. Mr. W. Carr left the service of the Corporation on Saturday last; and to-morrow the Mayor is to lay before the Town Council the terms of the undertaking which has been arranged between himself, as representing the Corporation, and Mr. T. K. Fox. It has taken a long time to settle the provisions of this interesting document, the purport of which we publish elsewhere, together with other information relating to the development of this extraordinary business. As we have already remarked, Mr. Carr's "strategic movement to "the rear" has left the Mayor and his advisers pretty much as they were; since it throws upon them the responsibility of taking action. It has had the good effect of bringing the sense of this responsibility home to them, however, as we learn that the Mayor is fully determined to take steps to clear up the matter, either in his official capacity or as a private citizen. This is as it should be; for the one solicitude of honest men in and out of Halifax at the present juncture must be that right should be done. Meanwhile, we do not mean to depart from the attitude of strictest reserve which we have taken up in regard to the merits of the affair, until the verdict of a competent final tribunal has been placed upon record. This determination, however—which is, after all, no more than the course pointed out by the sense of common justice as between man and man—will not prevent our expressing freely an opinion upon the methods by which the development of this business may be forced forward. Up to the present time there has been little to give satisfaction in the conduct of most of the parties concerned. Some allowance must, of course, be made for town councillors placed in such a delicate position as that occupied for some time past, while these matters have been coming to a head, by the members of the Halifax Corporation. Hounded on by public clamour to "do something," uncertain what course to adopt, doubtless agitated by opinions which they dare not openly avow, and some perhaps uneasily conscious through it all of the near approach of the November elections, the distracted town councillors have been beset with difficulties to which all their political troubles and vexations of ordinary times must seem like child's play in comparison. But they may be certain of one thing, which is that public opinion outside as well as in the town looks to them to remove this shadow upon the fair name of their corporate organism, and that speedily, lest those now free from blame fall under the same reproach.

We are pleased to learn that Mr. Alderman Wood, Chairman of the Gas Committee of the Leicester Corporation, has been unanimously selected by his colleagues on the Council for nomination for the office of Mayor at the forthcoming election. Mr. Wood is by no means the senior member of the Council—his first election only dating back to 1880; but he has exhibited such conspicuous ability in all his municipal work, that he has made himself specially worthy of selection to fill the highest office in the borough. His choice was, however, influenced to a very large extent by his success as Chairman of the Gas Committee. In the supervision of the gas undertaking he has displayed ability and energy that command cordial recognition; and when to these qualities are added the remarkable regularity and tact with which he discharges his duties, it will be acknowledged that the decision of the Council has been a wise one. Mr. Wood's interest in gas matters is by no means confined to the undertaking with which he is immediately concerned; and to all connected with the gas industry, and especially to gas engineers and managers, he has always shown himself to be a staunch friend.

Water and Sanitary Affairs.

THE eighth annual issue of the valuable "Analysis" in which Mr. Alfred Lass deals with the accounts of the Metropolitan Water Companies, has just been issued. The completeness and accuracy of this important work render it all that could be desired, as showing the position of the Companies in regard to their finances and their operations. The figures are vast, and bear witness to the energy with which the water supply of the Metropolis is administered. If we go back to the first year of Mr. Lass's "Analysis," we find the London Water Companies furnishing a supply to a population of less than four-and-a-half millions. This now becomes very nearly a million more. The volume of water has risen in the meantime, from an average of rather more than 142 million gallons per day to nearly 164 millions. The constant supply is now given to more than 372,000 houses, in place of less than 161,000. The capital, which was £12,690,000, is now £14,350,000; but economy has been so well practised that the amount per 1000 gallons has become 57·66d., instead of 58·60d. Rates and taxes, exclusive of income-tax, have made a sensible advance—rising from about £90,000 to £142,000. The cost of filtration is nearly doubled; while pumping shows a moderate rise. The net profit per 1000 gallons displays no very great advance; being 3·68d., as compared with 3·51d. Comparisons of this kind may be pursued to almost any extent, and will serve to throw light on many questions connected with the progress of the London Water Supply. Taken by itself, apart from any comparison, the present issue affords a fund of particulars which may be of special use to the new body which is about to take the reins of local government in the Metropolis. How soon the members of the County Council of London will turn their attention to the Metropolitan Water Companies, is of course problematical; but when they choose to enter on the subject, they will do well to study the tables of Mr. Lass. The responsibilities and troubles of the Companies are also indicated by the presence of two Acts of Parliament at the close of the book; the latest being that which is designed to "limit the powers of the Water Companies" in cutting off the supply when they cannot get their money. As in the former issues, the legal position of the Companies is shown, with regard to their rates of supply and other matters; quotations being made from their Special Acts. The statutory powers as to dividends are given, as set forth by Sir John Lambert. Information is thus at hand for the private consumer, as well as for those who take an interest in the Metropolitan Water Question on public grounds.

MESSRS. H. AND C. DAVIS AND Co., of the Metropolitan Gas-Stove and Engineering Works, Camberwell, have opened new show-rooms at No. 59, Queen Victoria Street, E.C.

IN *La Semaine des Constructeurs* there is published a recipe for preserving cast iron from rust while giving it a pleasing surface. The casting is to be thoroughly cleaned, and then washed in dilute acid. When dry the surface is to be well rubbed with a metallic brush or a file, and then painted several coats with raw (crude?) petroleum; care being taken to let each coat dry thoroughly before the next is applied. When the last coat is dry, it is to be well rubbed with a stiff hair brush, and the result will be a beautiful dull polish that will resist a high degree of heat, and will not be attacked by rust. The polish may be indefinitely preserved and improved by the occasional application of a single coat of petroleum followed by brushing, exactly as in the ordinary course of black-leading. If there is any value in this process, it ought to supersede the objectionable Berlin blacking for stoves of all kinds.

THE latest speculation in the way of distributing heat and power from a central station is the venture of the National (American) Superheated Water Company, in the city of Boston, Massachusetts. The partial success of the American steam-heating companies has been the incentive to this new departure; but it is claimed that the distribution of heat by means of hot water is more economical than steam. Supposing that it is desired to maintain a coil at a temperature of 350° Fahr., by means of water at 400° Fahr., and that a cubic foot of water, weighing at this temperature 58·63 lbs., is introduced into the coil for this purpose, in cooling down through 50° this water will liberate $54·63 \times 50 \times 1·0174 = 2728$ units of heat. The circulation of a cubic foot of water requires as much time as 9·87 cubic feet of steam. The isothermic volumes having the ratio of 1:13·7, and the ratio of velocities being 1:9·87, it follows that the consumption of steam must be 1·35 times that of water in order to produce the same effect. The mechanical work gives the final measure of the expenditure caused by the flow of a fluid; and it varies according to the cube of the velocity of the circulation of the fluid. If, therefore, the values 1 and 1·35 are cubed, we obtain, for the distribution of equal quantities of heat, a relative expenditure of 1:2·5 for water and steam.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 604.)

PRICES have fluctuated in most markets during the past week; the expectation of dearer money being the forcing-down factor. The Bank Directors made no change in the rate on Thursday; but money is in strong demand, and gold is being steadily drawn away, so that the Directors may be compelled to put the rate up this week. Business on the Stock Exchange has been pretty brisk; but the adjustment of an unusually heavy settlement has engrossed most attention. In the Gas Department there has been about the same degree of activity as the week before. Taking the Metropolitan Companies first, the leading feature has been the continued weakness of Gaslight "A." The stock was not dealt in at all on Monday; but on Tuesday the opening mark was 253. From this point it fell away gradually, till on Saturday it was done at 249½—the quotation showing a drop of 2. Electrical influences are probably the cause of this; and if the gas "bears" can manage it, we may perhaps soon have another run against the stocks. If so, the wise man will keep cool and watch his opportunity to buy. The "B" is 2 higher, and now stands at a far higher relative price than the "G"—the anomaly of which we have pointed out before. South Metropolitans have hardly been touched; two or three transactions, at moderate figures, being all. The same may be said of Commercial. The Directors' report and accounts were to hand on Saturday, and were found to be quite as satisfactory as had been anticipated, if not even more so. The market quotation, however, was not affected. The Foreign Companies have been stronger than the Home. Imperial Continental has been in good demand and very active; and the price has risen 1 more. Buenos Ayres debentures are also in increasing favour, and improved a point. All stocks marked *ex div.* show out better on adjustment of quotation. The Water Companies were more active in the earlier part of the week; but they quieted down later on. Prices have been well sustained, but have not advanced.

The daily operations were: Only moderate business in Gas on Monday; and prices did not run more than up to average. Buenos Ayres debenture, however, rose 1. Good business in Water, at firm figures. Gas was rather more active on Tuesday, but showed no particular strength. Gaslight "B" advanced 2. Water business was quieter. On Wednesday, dealings in Gaslight "A" were the bulk of the business in gas. Weakness was apparent; and the quotations fell 1. Business in Water was next to nothing. On Thursday, Imperial Continental was most favoured; and it rose 1. Other issues presented nothing remarkable. A few transactions in East London, and one in Lambeth, comprised the Water business. On Friday, there were a few dealings in Gaslight "A," at moderate prices; but better figures were obtained for some of the secured issues. Very little else was dealt in. In Water, the only transaction was one in New River. On Saturday, Gaslight "A" showed further weakness; and the quotation fell 1. Nothing at all was done in Water.

ELECTRIC LIGHTING MEMORANDA.

THE AFFAIRS OF THE MAXIM-WESTON COMPANY—MR. GEORGE OFFOR AND HIS INTERVIEWERS—A GLOWING PICTURE.

THE Directors of the Maxim-Weston Electric Company, Limited, have issued a statement of the affairs of the Company for the information of the hardly-used shareholders, in which (as published in the *Financial News*) some very peculiar things are said about the behaviour of the late Chairman and Managing Director, Mr. Hugh Watt, M.P. The present Board have only been in office a short period; but have seen enough of the Company's business to know that the position of the concern is very different from what it was represented to be in Mr. Watt's time. The assets, according to the report of the firm of accountants employed to investigate the books, appear to amount to £81,997; but of this no less than £40,737 is for patents. No provision had been made for the gradual extinction of this item, which, in the accountants' opinion ought to be depreciated at the rate of at least £2500 a year. Then it appears that there is a lot of the Company's manufactured goods in the hands of agents, very little having been sold; but credit in full has been taken in the books for it all, as though the value was so much actual book debts. Altogether, the report of the accountants as given abundantly bears out their conclusion that "the results of the trading have not been truly stated in the past, by reason of the non-provision for bad debts, and by the over-valuation of the stocks." The new Directors claim to have reduced the management expenses by £1000 a year; and they express the opinion that, notwithstanding the present unsatisfactory position of the Company, "with honest and attentive management, a good and profitable business may be carried on." To do this, however, sufficient working capital must be found to replace the money muddled away in the past. The question is whether anybody has sufficient confidence in the concern to advance the necessary funds to keep it going. The experience of the shareholders has been a bitter one; and it is no relief to them to know that they are only a few among the many confiding investors who have reason to repent having put their money into electric lights. It should be noted that Mr. Watt denies the accuracy of the statement published in the *Financial News*, so far as it relates to him; and his solicitors have written to that newspaper to state that the questions between

him and the Company "are about becoming the subject of proceedings in a Court of Law." Said we not rightly some time ago that electricians cannot keep out of the Law Courts, and can always find money for litigation if for nothing else?

Mr. George Offor seems to have lately succeeded to the office of peripatetic advertiser of electric lighting, *vice* Mr. Robert Hammond, compulsorily retired. Mr. Offor has profited by the experience of his predecessor, and goes to work in a more economical way. Instead of carting about the furniture for a drawing-room, and arranging these effective but costly "properties" in lecture-halls hired for the purpose of carrying on the electric light propaganda, Mr. Offor simply allows himself to be interviewed by the patient reporters of enterprising provincial newspapers. The advantages of this arrangement to all parties are obvious. The newspaper gets in a dull season as much of the new and readable matter as the editor chooses to find room for; the reporter does good business; and Mr. Offor gets a capital advertisement for nothing. He probably enjoys the freedom of the interview system, by which the communicator is able to fill his visitor's note-book with anything he pleases, reserving the right of throwing all blunders upon the innocent scribe. Mr. Offor is at present connected with the firm of Woodhouse and Rawson, Limited, after a varied experience of other and less successful electrical companies. His cue for the time being is to disparage all direct systems of lighting from the dynamo, and to recommend the battery transformer system "by means of which electricity may be laid down to your houses just as gas is, only with much greater safety, facility, and healthfulness," as he told a reporter of the *Newcastle Daily Chronicle*. Mr. Offor informed his auditor, and through him the public, that, with 20,000 lamps in regular use in Newcastle, the electric light could be supplied at a charge equivalent to 3s. per 1000 cubic feet for gas. This was a bold statement, even for Mr. Offor; but even so it failed to favourably impress the local public, which obtains high quality gas for 1s. 10d. per 1000 cubic feet. Indeed, the effort was completely thrown away; for not even the Editor of the newspaper which published Mr. Offor's statements believed that electricity could be supplied in the town at anything like his estimate of about 3½d. per Board of Trade unit, or even if this could be done that it would secure much custom in face of gas at less than two-thirds the price.

A London weekly journal supposed to be printed in the interests of inventors, and consequently given to imitations of the style and matter of the *Scientific American* and its fellows, recently came out with the following effusion, the source of which is not given. "When," asks this contemporary, "will London or Liverpool present a picture like the following:—From the shore of Staten Island New York on a dark night looks like fairyland; a thousand electric lights dancing from out of a sea of inky gloom, with here and there a cross, and there a crown, near which fireflies of huge dimensions start here and there with phosphor fires aglow; the streets a shimmer with silver, with calcined towers lumined against the unfathomable gloom beyond. Staten Island, as you approach it, is like a mountain touched by an enchanter's wand; the electric lights about the Nero show, and the docks at St. George, shining on the hill behind them, the blue and red and green fires streaming high above like a cloud of brilliant colouring." This is quite too delicious, both to read and think about. The passage is manifestly taken "all standing" from a New York newspaper, but is incomplete. If one could lay hands upon the original, it would be found to tail off into an artless recommendation of some place of public resort, admission to which is obtainable for a small payment, and from which the deliriously beautiful panorama described may be seen to the best advantage. With one phrase of the composition we cordially agree. It is that in which the poetic writer describes the electric light as "dancing from out of a sea of inky gloom." That is precisely the effect which was produced by the arc lamps once used to light the Thames Embankment and certain of the City bridges over the river, to the confusion of pilots responsible for taking craft up and down the stream after dark. It may look pretty from a long way off; but it is eminently a case in which "distance lends enchantment to the view." London and Liverpool have both tried these marvellous "dancing" lights, and neither city likes them. It is amusing to see how, when electric lighting is to be vaunted, all unfavourable experience is ignored.

DEATH OF MR. GRIFFITH THOMAS.—The death is announced as having taken place on the 20th ult., at his residence at Englefield Green, in his 82nd year, of Mr. Griffith Thomas, the Deputy-Chairman of the Commercial Gas Company.

THE ARTESIAN BORING AT EALING.—We learn that Messrs. Le Grand and Sutcliffe have now reached a depth of 350 feet with their artesian boring at Ealing, to which reference was made in the *JOURNAL* last week, and that already there are indications of a good supply, as water has risen to within 55 feet of the surface.

NORTH OF ENGLAND GAS MANAGERS' ASSOCIATION.—The twenty-third half-yearly meeting of this Association will be held at the Gas Offices, West Hartlepool, on Friday, the 12th inst., under the presidency of Mr. T. Bowor, Engineer and Manager of the West Hartlepool Gas Company. An address will be delivered by the President, and a paper on "Modern Methods of Increasing Gas-holder Storage" will be read by Mr. J. Wright, of Stockton. If time permits, a short sea trip will be made round the port; after which, at the invitation of the President, the Association will dine at the Royal Hotel, West Hartlepool.

THE FUTURE OF ARTIFICIAL LIGHTING.

It is an old observation that invention goes in cycles, the reason for which is obvious. Somebody startles the world with a novel device, perhaps embodying a discovery, or only showing how a well understood object may be attained by a new and simple process. Forthwith general attention is directed to the same line of effort; and the single innovator is followed by a pack of imitators and rivals. It must frequently occur to a thoughtful observer of the development of the arts and industries, when he sees patentees flocking after one another with modifications of a particular idea, until the very name of the subject of their attentions becomes a weariness to the flesh, that even at such times patient workers in obscure places may be preparing the next surprise for the world; and he is often tempted to imagine what may be the nature of the forthcoming attraction. Inventors' crazes follow one another with such regularity, that an observer is sure to be right in dwelling upon the probability that a new departure of some kind must be in preparation while its predecessor is still engrossing the public attention. In invention, however, the only safe thing to look for is the unexpected. It is impossible to foresee the line that inventive effort will take; but it is tolerably certain to break out in the least likely places. In gas engineering we have witnessed many waves of invention flow and ebb of late years; and nobody can say when or where the next will arise. Gas inventions may for our immediate purpose be divided into two great classes, in both of which there has of late been considerable activity. One class will embrace all the inventions connected with gas making and gas-making appliances, which generally originate with professional men more or less identified with the industry. The other includes all devices designed for the utilization of gas; and in this field the inventors do not belong to any particular order of the community. Professional gas engineers do not bulk largely in the list of patentees of successful gas-burners, engines, stoves, and similar commodities. This is rather a remarkable fact; and it would be possible to draw from it some very uncomplimentary conclusions as to the interest commonly taken by gas engineers, properly so called, in the uses of the article to the production of which the best of their energies are devoted.

The object of this article is not to indulge in general reflections of this kind, however; but to discuss one or two points connected with the present use of gas for illuminating purposes. In this branch of gas utilization there have been cut two well-defined grooves, which apparently include all progressive efforts. One is the improvement of the lighting power of gas by heating it and the air required for combustion, preferably by the recuperative process; the other is the production of light from gas by so-called incandescence methods. There has been plenty of effort devoted to increasing the amount of lighting duty that may be obtained from the combustion of coal gas; and this endeavour has been very conspicuously crowned with success. But it has all gone in one or the other of these ruts. We have always favoured the heat recuperative principle as applied to gas-lamps; and we have never felt convinced of the value of its rival, brilliant as its promise has been. The time has come, however, to ask whether it must be taken as settled that the production of the best light that can be possibly obtained from gas must be by one or the other of these methods. To say truth, it is becoming wearisome to see how patentees continue to flutter round the high-power lamp, like so many infatuated moths. To partly change the figure it may be said of this craze that the crowd of inventors, again like moths, persistently waste their time and strength in struggling to get at this gaudy flower, the honey of which has been abstracted long ago by others who were earlier afield. Only the poorest sustenance remains for the late comers. Can they not discover some new pasturage?

There are indications that some of the keenest minds among the votaries of physical science are at the present time engaged in the study of the fundamentals of the production of artificial light; and it would not be surprising if the next great move in the application of science to this object should be of a nature to astonish electricians not less than gas engineers. For some time past the halo that once surrounded electric lamps, both arc and incandescent, has disappeared before the scrutiny of the philosopher. There are many now who flatly refuse to electricity, as at present applied, that claim to be regarded as the "light of the future," which has consoled its partizans amid so many present disappointments. They have come to regard electric lighting as little higher in the scheme of development than gas, and to deny finality to any such round-about method for converting the energy of coal into light. The gas maker has been called unscientific, because he merely converts the raw material, coal, into gas which, when purified, is distributed for the purpose of affording light by its combustion with air. The electrician has called himself scientific, because he burns the coal for raising steam, and uses the steam for actuating an engine, whose power he converts into electric energy, and this again into heat and light for his lamps. If, according to Mr. W. H. Preece, 1000 watts have been delivered from a dynamo driven by an engine requiring a fuel consumption of only 2lbs. of coal for this duty, and if modern incandescent lamps only absorb 3 watts per candle power, it follows that these 2lbs. of coal thus used are capable of giving the light of 333½ candles by electrical incandescence. Converted into gas, 2lbs of the best coal cannot be credited with yielding more than 9 cubic foot of nominally 16-candle gas, which in the best regenerative lamps will not give more than 90-candle power of actual light. Thus stated, and neglecting all other considerations,

electric lighting is capable of giving a higher duty from the raw material—i.e., it is more scientific—than gas lighting. Of course, to arrive at such a conclusion, which is not borne out by reference to actual experiments in which practical and commercial considerations assume their natural importance, one must be content for the time to shut one's eyes to everything but the purely philosophical aspect of the problem of lighting. Continuing in this point of view, however, we shall find that electric lighting is only just barely more acceptable than gas lighting. The natural philosopher looks down upon all known methods of procuring light by combustion or incandescence as indirect, empiric, wasteful, and, in short, altogether despicable in the scientific eye. Light, he tells us, is due to rapid vibrations of the ether which fills cosmic space. If we turn upon him and ask what he means by this term ether, which physicians use in a different sense, we only gain a shallow victory. He will perhaps admit that he has imagined the matter itself, and has named it; but he will utterly rout us and silence all objections by asking in turn, if there is nothing to undulate how it is that the light of the sun reaches us through the void that separates his atmosphere from ours? Thus reduced to impotency, we must listen to the philosopher's remarks with what patience we can muster. He will go on to assure us that to him the word ether means in this connection nothing more than "that which undulates." We may call it what we please; the only thing the natural philosopher will insist upon being that, so long as the undulatory theory of light holds good, we accept the existence of his hypothetical substance as explaining how light-waves travel through interplanetary space. Light being an undulatory movement, therefore, the question is how to produce this movement. It is the extremist pitch of vibratory movement, to which the sharpest vibrations of air that we recognize as sound are sluggish. Flames, incandescent wires, give light because they set up some of these very rapid vibrations of the ether; but the number and value of the vibrations that we can see are the merest fraction of all the vibrations in which the potential energy of the matter concerned is consumed. Dr. Oliver J. Lodge has been discoursing eloquently upon this subject in terms which we reproduce elsewhere. His words are worthy of the most careful study, and suggest infinite reflections. They recall to us, in the most forcible way, the truth that in producing light, either by electricity or by direct combustion, we waste by far the greater part of the material which we consume for this purpose. We cannot separate light from heat, much as it would be to our advantage to do so. Heat without light we may have, as in a can of hot water. Light with comparatively little heat we may also have, as in the case of the incandescent electric lamp. To produce the latter, however, there has been a great deal of heat developed in the boiler furnace; and the lamp is in reality only a part of this transported to a distance at a heavy charge for carriage. With a gas-burner we have both light and heat; but, having developed a minimum of heat for the visible effect, we know that, if we increase this heat by a comparative trifle, the light will be augmented in a very much greater ratio. This concentration of heat, and corresponding increase of the visible vibrations, obtains its present superlative in the electric arc, where the energy of a horse power, which may be spread over a square foot of furnace area at a low temperature, is concentrated into a space of three-eighths of an inch square. Yet the philosopher is not satisfied with this. He calls it still wasteful; and will not be satisfied with anything short of the presentment of light vibrations separated, as cream is separated from milk, from the great heat vibrations on the summit of which they float into our cognizance.

Will this ideal of a cold light ever be realized? Who can say? Strange things have been done ere now, before and since the time when Comte, who pretended in his way to know everything that man could do, made himself an example of presumption by laying down the proposition (which then appeared incontrovertible) that we should never be able to ascertain what the stars are composed of. The eye of the philosopher is turned once more upon the lowly glow-worm, and the strange West Indian lantern-fly. Why and how do these creatures show their light? That is the question upon the answer to which the future of artificial lighting is held to depend. What is the mechanism of this cold incandescence which land and marine insects display in such perfection? The jelly fish is as cold as the water in which it floats, and of which it is chiefly composed; yet when agitated in the dark, it emits a startling flash—how? Here then, according to the newest philosophy of the subject, the "light of the future" is hidden away. Without effort, and so far as we can tell, with little or no waste, the so-called phosphorescence of insects is kept up. It is possible that this peculiar light really is due to the excitation of luminous waves, [without the simultaneous production of those heat-waves which cost us so much to make, and which we do not want. If so, how is it done? The subject is very fascinating, possibly because it seems so hopeless to seek a solution to the problem it presents.

For the immediate present, however, as we began with the consideration of gas lighting, so we will conclude with the same. If the reflections set forth in this article teach anything, it is that, while increasing the light vibrations of a centre of gas consumption by heightening its temperature, a profitable field for effort may be found in concentrating the effect. How this concentration may be practised cannot, of course, be stated. This must be the opportunity for the inventor. It is sufficient to show that in concentration may be found the next great advance in the development of the illuminating power of gas-flames; and that this is the truth may be gathered from the various analogies cited.

THE HALIFAX GAS SCANDAL.

ALTHOUGH no official statement has been made during the past week respecting the "gas scandal" at Halifax, matters are speedily approaching a crisis, and public feeling in the district has become very strong indeed. The opinion prevalent among the ratepayers generally is overwhelmingly in favour of the Mayor signing the indemnity. He has decided to bring the subject before the Town Council to-morrow (Wednesday) evening; and will ask the members to pass a resolution approving of his appending his signature. The matter will be discussed in presence of the reporters; and his Worship will, it is expected, be prepared to state at the meeting certain grave reasons justifying the course he wishes to take. But our local correspondent has good reasons for thinking that Alderman James Booth (the Mayor) has fully made up his mind to go beyond this; and should a majority of the Council disapprove of his signing the indemnity, he will at once accept the whole responsibility, and sign it on his own account. He is even fully prepared, it needs be, to go to the extent of resigning his office and appealing to the ratepayers. The indications, however, are that a large majority of the Town Council will support him.

During the week, for about four days, Mr. Ellis Lever's private secretary was at the Town Hall, examining and comparing papers and documents relating to the coal contracts; and there is a prevailing opinion in the district, which is somewhat angrily discussed in many quarters of the town, that it is now high time that some specific charges should be made, if there are any to make, and that the matter should be brought to daylight. On Friday, Mr. Ellis Lever, Mr. T. K. Fox, and their solicitor, had a long interview with the Town Clerk; and it is understood all round that specific charges will be made, and made public, by Thursday morning next. There are three persons against whom Mr. Fox is prepared to prefer certain specific charges. One of these is a prominent member of the Halifax Town Council, and another is an extensive "middle-man" in the coal business. The name of the third has already been openly stated to be Mr. William Carr. It is believed to be Mr. Fox's intention to bring charges against these gentlemen both individually and conjointly.

The full text of the indemnity, the terms of which were stated in the JOURNAL last week, have now been fully agreed upon. It is as follows:—

This Indenture, made the day of one thousand eight hundred and eighty-eight, between James Booth of Halifax, in the county of York, Esquire, the Mayor of the said borough of Halifax, of the one part, and Thomas King Fox, of Silkstone, near Barnsley, in the said county, commercial traveller, of the other part.

Whereas the Corporation of Halifax are the proprietors of the works which supply the borough of Halifax with gas, and the same are worked and managed by them or their officials. And whereas the said Thomas King Fox has written certain letters to Keighley Walton, Esquire, the Town Clerk to the said borough of Halifax, concerning the supply of coals to the said gas-works. And whereas the said Corporation expressed a desire to have the said statements in the letters of the said Thomas King Fox fully and thoroughly investigated, and requested him to furnish them with any information he might have in his possession relating to the same, which the said Thomas King Fox declined to do unless he received a complete indemnity against all fines, costs, charges and expenses, which he might incur, or moneys he might have to pay in obtaining proof of, and in proving the same, provided he successfully established the truth of the same. And whereas the said James Booth has unconditionally accepted the offer of the said Thomas King Fox, and has agreed to give him his personal indemnity and undertaking hereinafter contained.

Now this Indenture witnesseth that, in consideration of the premises, it is hereby covenanted, agreed, and declared, by and between the said parties hereto, as follows:—

1. The said Thomas King Fox shall, on the signing hereof, state in writing to the said James Booth the name or names of the person or persons referred to in his letters as the objects of the charges therein referred to, and will make libellous charges of such a nature as will entitle the parties named to bring an action or actions against the said Thomas King Fox.

2. On the said Thomas King Fox so stating the name or names of the said person or persons, and the charges so referred to as aforesaid, the said Corporation shall, if the said person or persons be a servant of the said Corporation, insist upon the person or persons named bringing a civil action for libel within one calendar month from the date hereof against the said Thomas King Fox, and if the said person or persons be not a servant of the Corporation, shall call upon the said person or persons named to bring a civil action against the said Thomas King Fox, for the purposes of having the said charges fully and completely investigated and inquired into before a Judge of the Queen's Bench Division of the High Court of Justice and a Special Jury, or Judge of the Division without a Jury, as the said Thomas King Fox shall think fit and the Court allow. The said Thomas King Fox shall not plead any privilege as a defence to any such action, but shall justify the said charges. But if criminal proceedings are taken against the said Thomas King Fox, he shall be at liberty to plead that the charges were made in confidence, and as a privileged communication; it being the intention of the parties hereto that the charges should form the subject of investigation in a Civil Court.

3. In the event of the plaintiff or any of the plaintiffs in the said proceedings to be taken as aforesaid failing to obtain a verdict and judgment for damages of £10 or upwards and costs, or, in the event of criminal proceedings, an acquittal or verdict of not guilty, then and in every such case the said James Booth hereby for himself, his executors and administrators, expressly covenants with the said Thomas King Fox that he the said James Booth, his executors or administrators, will save harmless and keep fully indemnified the said Thomas King Fox, his estate and effects, from all costs (as well between solicitor and client as between party and party), charges, disbursements, and expenses of what nature or kind soever, which he or his duly authorized solicitors and agents shall properly incur (as well before as after action brought) in, about, or relating to obtaining information, the preparation or conducting of his defence to the said proceedings, and the bringing of the same to trial, in a full, complete, and proper manner; it being the full intention and meaning of these presents that the said Thomas King Fox shall not be put to or incur any expense personally in the event herein provided for, and that what-

ever expense he may incur or be put to he shall be fully recompensed, reimbursed, and indemnified by the said James Booth.

4. And the said James Booth, on behalf of the said Corporation of Halifax and their officials, covenants and undertakes that every reasonable opportunity and facility shall be given to the said Thomas King Fox and his solicitors for inspecting all the Corporation books relating to the gas-works, and also all tenders, contracts, and papers relating to or affecting the working and management of the said gas-works, and will place no obstruction whatsoever in the way of the said Thomas King Fox, but, on the contrary, will give him every opportunity and facility for making a complete and thorough investigation into the matters complained of as hereinbefore mentioned.

5. In case the said plaintiff or plaintiffs in the said action for libel shall obtain a verdict and judgment for damages of £10 or upwards, and costs, or in the event of criminal proceedings a verdict of guilty against the said Thomas King Fox, then in such case the indemnity herein contained shall be null and void; otherwise the same shall remain in full force and effect.

6. Provided also, and it is hereby agreed, that the said James Booth shall pay to the said Thomas King Fox the sum of one hundred pounds, and for agreed costs, charges, and expenses before action, and if no proceedings be taken against the said Thomas King Fox within one month from the date hereof, then the said James Booth shall forthwith pay the said sum of one hundred pounds to the said Thomas King Fox or his solicitors.

In witness whereof the said parties to these presents have hereunto set their hands and seals, the day and year first before written.

Notes.

ESTIMATING THE VOLUME OF GAS IN PIPES OR FLUES.

The subject of the difficulty attending the estimation of combustion or generator gases by means of mechanical appliances has lately been dealt with by the *Chemiker Zeitung*. It appears that hot gases are liable to destroy the apparatus; ash and dust may render them inefficient; and, further, they ought to occupy the whole cross-section of the flue, as in the various parts of the flue the gas will have a different velocity. In Munich the estimation of the volume of the smoke gases from the kilo. of coal is done in the following manner:—If, for instance, the combustion gases have a percentage composition of 6.12 of carbonic acid, 0.89 per cent. of carbonic oxide, 0.10 per cent. of hydrogen, 14.21 per cent. of oxygen, and 81.60 per cent. of nitrogen, and if the coal used contains, according to combustion, 81.6 per cent. of carbon, then one cubic metre of the gas (contained as carbonic acid or carbonic oxide), at 0° C. and 760 mm. pressure, contains 0.5364 kilo. $[0.0612 + 0.0089] \times 0.5364 \text{ kilo.} = 37.60 \text{ grammes of carbon.}$ Now, 1 kilo. of coal contains 81.6 per cent. = 816 grammes of carbon, and will therefore yield $816 \div 37.6 = 21.7$ cubic metres of dry smoke gases. These figures are sufficient to estimate the loss of heat from 1 kilo. of the fuel.

THE PROBLEM OF ARTIFICIAL LIGHTING.

In the course of a series of articles setting forth the modern view of electricity, Professor Oliver J. Lodge arrives at the conclusion that "light is an electrical disturbance, and that light waves are excited by electrical oscillations;" which conclusion he believes must ultimately have a practical import. Professor Lodge remarks that our present systems of making light artificially are wasteful and ineffective. We want, he says, a certain range of oscillation—between 7000 and 4000 billion vibrations per second; no other is useful to us, because no other has any effect upon our retina. But we do not know how to produce vibrations at this rate. We can cause strings to vibrate one or two hundred or a thousand times per second, with the result of emitting a pure tone of definite pitch; but to get much faster rates of vibration, we have to fall back upon atoms. We can make atoms vibrate by what we call heating the substance; but the vibrations are then infinite in number and mode, and only a few of them are of use to us. As we do not yet know how to separate the vibrations that are useful to us from the great majority, we are obliged to excite them all together, at an obviously unnecessary expense. We take a lump of matter—say, a carbon filament or a piece of quicklime—and by raising its temperature, we impress upon its atoms higher and higher modes of vibration; not transmuting the lower into the higher, but superposing the higher upon the lower, until at length we get such rates of vibration as our retina is constructed for, and we are satisfied. The process is evidently wasteful, and indirect and empiric. We want a small range of rapid vibrations; and we know no better than to make the whole series leading up to them. It is, says Dr. Lodge, "as though, in order to sound some little shrill octave of pipes in an organ, we were obliged to depress every key and every pedal, and to blow a young hurricane." If this remark applies to the incandescent electric lamp and to lime light, it also applies with even greater force to lights of combustion, in which a great amount of radiation is produced but is not wanted: the only result really desired being the minute, almost infinitesimal fraction of the whole effect which enables us to see. In short, the production of light-waves, without any others, is held out by Professor Lodge as the problem of artificial lighting for the future.

THE QUALITIES OF A GOOD ROPE.

In an article on rope-making credited to a German periodical, but quoted in *Iron*, it is remarked that the appearance of a hemp rope affords to an experienced eye very fair indications of its quality. A good hemp rope is hard, but pliant, yellowish or greenish grey in colour, with a well-defined silvery or pearly lustre. A dark or blackish tint indicates that the hemp has suffered from fermentation while curing; and brown spots show that the rope was spun while the fibres were too damp, and is consequently weak and soft in the stained places. Sometimes a rope may be made up

of inferior hemp on the inside, while upon this, as a core, good yarns are overlaid. This fraud may, however, be detected by unlaying a portion of the rope; and it generally betrays itself in use, if not otherwise discovered. Another variety of inferior rope is that made of short fibres; or the strands may be of unequal length or unevenly spun. In the first case the rope has a woolly or rough appearance, on account of the number of projecting ends of fibres; and in the latter case the irregularity in laying is easily perceived upon inspection by anyone who knows what a good rope should look like. The combustion test for ascertaining the purity of Manilla rope has been published, but may be usefully repeated here. It consists in unravelling some of the fibre of the rope to be tested, and forming it into a loose ball, which is to be completely burnt upon a clean surface such as an iron plate. Pure Manilla hemp burns to a dull greyish-black ash; Sisal leaves a whitish-grey ash; combinations of Manilla and Sisal show themselves by gradations of the greys.

THE CALORIMETRY OF COAL—A CORRECTION.

In the JOURNAL for Jan. 10 last, there appeared a "Note" upon a calorimetric experiment with English coal conducted by MM. Scheurer-Kestner and Meunier-Dollfus, made at the request of Mr. Bryan Donkin. The results of the experiments are given as they were printed in the *Comptes Rendus*. It has since been discovered, however, that this statement is wrong, owing to the fact that, by an error of calculation, the initial temperature of the feed water was deducted twice. The net duty of the coal being 10.44 of water at 0°C. per unit of fuel, the total quantity of heat absorbed by the kilogramme of evaporated water was 651 calories instead of 632.5. Consequently, the number of calories contained in a kilogramme of water is 6796, and not 6603. The corrected statement of the distribution of heat is therefore as follows:—

In the steam	6796 calories, or 74.68 per cent.
In the combustion gases. . .	481 " " 5.28 "
In the aqueous vapour of the combustion gases . . .	252 " " 2.76 "
Loss by external radiation . .	395 " " 4.34 "
	7924 calories, or 87.06 per cent.
Unaccounted for	1175 " " 12.94 "

Total . . 9099 calories 100.00 per cent.

The correction appears as a preface to the full report of the experiments presented as a memoir to the Société Industrielle of Mulhouse, which has been printed separately as an extract from the *Bulletin* of the Society.

GAS-FIRES.—Messrs. T. Fletcher and Co., of Warrington, have brought out this season a series of entirely new gas-fires, both in principle and design. The heat, before passing into the chimney, circulates in a radiating canopy, with internal convoluted and studded flues. This radiator utilizes the waste heat very effectively, and the whole stove becomes a powerful radiating medium. In larger sizes, the same principle is further carried out by the waste heat being conveyed down the side of the stove, through a hollow fender, and up a return flue to the outlet at the back. The stoves are finely finished in Italian Renaissance style, and present a very handsome appearance.

PROHIBITION OF THE IMPORTATION OF SACCHARINE INTO PORTUGAL.—A despatch dated the 18th ult. has been received from Sir G. F. Bonham, Her Majesty's Chargé d'Affaires at Lisbon, enclosing copies and translation of a decree which had been published in the *Official Gazette*, prohibiting the importation into Portugal and the islands, except under certain specified conditions, of saccharine, and of any articles of food into the composition of which it enters. The following is a copy of the translation of the decree in question:—"Article 1. The importation of saccharine, whether pure or mixed with any article, and likewise any articles of food that may contain the same, into the continental part of the kingdom, or into the adjacent islands, is prohibited, except under the conditions set forth in the following article. Article 2. Chemists will be allowed to import this product after having obtained the permission of the Government, who must take the advice of the General Board of Customs. For the intents and purposes of this article, importers will have to make a petition, stating the amount of saccharine which they wish to import, and through which custom house they wish to do so."

WATER PURIFICATION BY IRON.—In a pamphlet written by Mr. E. Devonshire, Assoc. M. Inst. C.E., the Resident Engineer and Manager of the Antwerp Water Company, he gives an account of three years' experience of water purification by means of iron in Anderson's revolving iron purifier; this being the period during which the system, in its complete form, has been in operation at Antwerp. The process, which has frequently been referred to in our columns, is fully described by the aid of some well-executed lithographical diagrams of the various appliances employed; and the analytical results of the treatment of the water are given in the second part of the pamphlet. The author states, as the result of his observations, that waste or scrap iron, when used in revolving purifiers, is not less efficient than spongy iron (the material originally employed), while it is more suitable in form, and cheaper in application. The little book is issued by Messrs. Easton and Anderson, of London and Erith, and merits the attention of water engineers from the fact that it contains particulars, gleaned from the author's personal experience of the working of the process he describes, which they may find of much practical value.

Communicated Article.

THE GUIDE-FRAMING OF GASHOLDERS.

FOURTH ARTICLE.

As some time has elapsed since the appearance of the third article on the above subject, it may be as well to briefly recapitulate what has already been advanced.

The first article was an inquiry into the general principles involved in the stability of gasholders, and the effect produced by shortening the guide-framing. It was proved that in any gasholder the depth of each lift must be equal to at least one-seventh of the diameter; and that *under certain conditions* it may be admissible to reduce the height of the guide-framing to that of the depth of the outer lift only, but no shorter.

The second article treated of the first condition necessary for the stability of gasholders having reduced guide-framing—viz., that *each lift must be rigid in itself, and unable to distort under the strains induced*. We gave rules for determining the magnitude and character of the extra strains induced by this method of construction, illustrated by examples; and found as general results that in three-lift gasholders the guide-framing must reach *at least as high as the top of the middle lift* when fully up (fig. 32), otherwise the holder would be unsafe, and that double-lift gasholders

Fig. 32.

Fig. 33.

could be made with the guide-framing stopping short at the outer lift, providing the depth of each lift is fully one-fourth of the diameter (fig. 33).

In the last or third article, we considered the second condition necessary for the stability of gasholders with foreshortened guide-framing—viz., that *the guide-framing itself must be perfectly rigid and unyielding*, otherwise it will admit of the projecting lift or lifts swaying over dangerously. We resolved that it was practically a matter of strength, or of determining the strains, and then designing the guide-frame to meet them. We divided gasholder guide-framing into two distinct classes—viz., the simple cylinder and the multipost types. (See Note N.) We then demonstrated the principles to be observed in finding the strains, and deduced simple, practical rules for gasholders of the former or perfect cantilever class (figs. 32, 33, and 34.)

Fig. 34

Fig. 35.

We will now treat of the second class or independent post type (fig. 35), and then apply the rules to a few examples; concluding with a summary of the whole question.

GASHOLDERS OF THE MULTIPOST TYPE.

In determining the strains on gasholders of this type, we are met with the difficulty of variety in design. We have, indeed, everything from the simple gasholder with vertical posts and no connecting girders or ties whatever, to that having one, two, three, and occasionally four tiers of girders; the girders being sometimes of wrought iron, deep, strong, and well-attached to the columns, or they may be poor frail things, insufficiently attached, perhaps of cast-iron open work, practically useless except for ornament and the bare appearance of strength. Then, again, the girders may be either upright, or lying on their sides so as to form a stiff ring; or both plans may be blended in one structure. Then, the columns or standards may be of any variety of shape—round, tripod, or T shape; I shape, diamond, or square (figs. 36, 37, and 38, on next page)—all having their peculiarities and influence on the strength of the structure as a whole. They may be of cast iron, wrought iron, or steel; arranged in pairs or singly; either with or without diagonal rods between them; and perhaps with horizontal bracing at the top—Paddon's ties. We then have the excess of strength in the gasholder bell in cups and curbs lending horizontal stiffness to the frame. (See Note O.) All this makes it very difficult to give general rules which will apply with equal truth to every variety; but we may lay down the following principles to aid us in classifying the different features and their influences.

Fig. 36.

Fig. 37.

Fig. 38.

The strength of gasholders may be considered to vary as—

1. The number of columns or standards.
2. The transverse strength of one column taken independently of the rest.
3. The total overturning pressure.
4. The number of tiers of girders and their stiffness, and the extent of the bracing (if any) between the columns.
5. Surplus strength of gasholder bell, in cups and curbs—stiffness generally—to resist distortion. The more cups and curbs, the greater the resistance to distortion.
6. The workmanship, material, nature of junction, and design of details generally.

We can construct formulæ embodying these variations which will give the bending moment each column or standard is called upon to resist. It is then, of course, very easy to proportion the column to meet this bending moment, as will be shown when we apply the formulæ to examples.

Let D = the diameter of the outer lift (feet).

d = the total depth of gasholder when right up (feet).

N = number of columns.

C = constant, varying according to design and wind pressures, thus: For gasholder having guide-framing the full height—

3 lifts and 3 tiers girders	=	300
3 " 2 " "	=	250
2 " 2 " "	=	200
2 " 1 " "	=	150
1 " 1 " "	=	100

In applying these constants, they must be modified as follows:—If the gasholder be well sheltered from wind all round, 25 per cent. may be added to them. If, on the other hand, it is exposed to great wind pressure, 25 per cent. should be deducted; and in special cases, where erected on the coast (and unprotected in any way from furious gales), they may be reduced as much as 50 per cent., as it is absolutely necessary to err on the side of safety, to allow for contingencies even under the best supervision.

Having modified the constant according to wind pressure, call it C_1 ; and then still further modify it as follows:—

If diagonal ties, add from $\frac{1}{2} C_1$ to $\frac{3}{4} C_1$, according to strength and attachment of same.

If curbs and cups are very strong, add $\frac{1}{10} C_1$.

If girders are shallow, and not well attached or bracketed to columns, deduct $\frac{1}{4} C_1$ to $\frac{1}{2} C_1$.

If standards lack lateral or side stiffeners, deduct $\frac{1}{2} C_1$.

If workmanship or materials are of inferior character, deduct $\frac{1}{2} C_1$ to $\frac{3}{4} C_1$. (This embraces unfair holes and bad riveting; loose fitting bolts, instead of rivets; work unduly strained by drawing together; ties not taut; junctions and details generally badly designed and proportioned; guides out of plumb; rollers badly adjusted, &c., &c.)

Then M the bending moment at foot of one column or standard (in foot-tons)=

$$\frac{D \times d^2}{N \times C}$$

Having determined this, we know, of course, that the moment of resistance, R , of the column or standard must be equal to it.

R , for ordinary round cast-iron columns = approximately,

$$\frac{Ad}{1.6} \text{ foot-tons.}$$

Where, A = the sectional area of column (in square inches),

d_1 = the diameter of column (in feet).

R , for latticed standards, or web plate standards of symmetrical cross-section, wrought iron = $5 A d_1$, steel = $8 A d_1$.

Where, A = effective sectional area of back flange (square inches),

d_1 = depth of standard from front to back (feet).

NOTE.—The constants 5 and 8 may well be reduced if the standard be of the lattice type and the "pitch" of the lattices is excessive.

Cast-iron standards, with open webs and various thicknesses of metal

are in every way inferior to wrought iron; so that we need not consider them. The same remark applies to cast-iron girders.

Where the section of a web-plate standard is unsymmetrical, it requires special treatment. The resistance of one flange must be multiplied by its distance from the centre of gravity of the cross section of the standard (assumed neutral axis), then double of this product will give approximately the resistance of the standard to bending (R).

Gasholders with reduced guide-framing should have diagonal ties added to the guide-framing, of sufficient strength to bring them under the cantilever cylinder type described in the third article; and the several lifts must be stiffened up to meet the extra strains, as directed in the second article, also tangential as well as radial rollers should be adopted to assist in getting a good fit and grip between the holder and the guide-framing.

NOTE N.

Other forms of gasholders, besides those treated of in these papers have been proposed; but they have not met with much favour. Notably, the gasholder having the guide-framing attached to, and supported by, the tank only (see fig. 41), and having a domed bottom tank, as described by Professor Otto Intz.* Also

Fig. 42.

Fig. 43.

the central column gasholder and the annular gasholder (see figs. 42 and 43) treated of by Barker, Wyatt, Meigel and Couffinal, and others. There are so many things against them that they are not likely to make very rapid strides. We may at some future time consider these forms of gasholders more minutely.

NOTE O.

Gasholders without any connection between the standards are never made now; so we need not consider them. Gasholders with twin columns are rare; for all practical purposes, in determining the strains, the columns may be treated as equally divided round the circle, instead of being in pairs; and then the rules which apply to the ordinary construction will likewise apply for this. It is an expensive and unnecessary mode of construction. The object in making them in pairs appears to be to get strength with several light columns, in preference to half the number of heavy ones, as well as to avoid cutting up the gasholder into so many narrow bays. Frail cast-iron girders with open webs may also be struck out, as being unreliable and out of date.

THE MANAGEMENT OF THE MARYPORT GAS-WORKS.—The Maryport Trustees have appointed Mr. E. Smithard, of Derby, as successor to Mr. D. Irving in the management of their gas-works; the latter gentleman having, it may be remembered, been selected to fill the position of Resident Engineer of the Stapleton Road works of the Bristol Gas Company. There were originally 52 applications for the Maryport appointment (which was advertised in the JOURNAL for the 11th ult.); and these were brought down to three—the final selection being as above stated.

THE QUALITY OF THE NEW GAINSBOROUGH WATER SUPPLY.—Dr. Percy F. Frankland has called our attention to a slight error in the last line but one of the paragraph under the above heading which appeared in the JOURNAL for the 18th ult. It was there stated that, according to his analysis of the water, the total solid matter in it was 49.97 grains "per gallon." These figures relate to "parts per 100,000," as do those contained in the preceding line of the paragraph. This would be equivalent to 34.98 grains per gallon, which compares well with a report which Dr. C. Meymott Tidy has submitted, giving the quantity as 36.77 grains, nearly the whole of which consists of the carbonates and sulphates of lime and magnesia, with some chlorides of sodium and magnesium. As regards dissolved organic matter, Dr. Tidy adds that the water must be considered as one of great—almost exceptional—purity.

SOCIETY OF ENGINEERS.—Last Tuesday the members of this Society, with a number of friends, paid a visit to the locomotive, carriage, and waggon works of the South-Western Railway Company, at Nine Elms. Among the party were Mr. A. T. Walmisley (President); Messrs. J. R. Baillie, H. Adams, and R. Harris (Vice-Presidents); Messrs. Perry F. Nursey, C. Gandon, and H. Robinson (Past-Presidents); Messrs. Chris. Anderson, J. H. Cunningham, W. A. Valon, and J. W. Wilson, jun. (Members of Council); Mr. Alfred Williams (Hon. Sec. and Treasurer); and Mr. G. A. Pryce Cuxson (Secretary). These famous works, which cover 45 acres of ground, were originally designed by the late Mr. Joseph Beattie, and at that time considered very complete, have been, owing to the increase of traffic and stock, considerably altered and enlarged by Mr. William Adams, the present Superintendent, and employ between 2000 and 2500 men. The party were entertained at luncheon by Mr. Adams.

* See Appendix to The Gas Institute Transactions, 1885.

Technical Record.

EASTERN COUNTIES GAS MANAGERS' ASSOCIATION.

A meeting of gentlemen having the management of gas-works in the Eastern Counties was held at the Gas-Works, Peterborough, last Wednesday, in accordance with the circulars recently issued by Mr. H. Wimhurst, of Sleaford (*ante* pp. 369, 510), to consider the feasibility of forming a Gas Managers' Association for the Eastern Counties. Mr. WILLIAM BARRATT (Grantham) having been elected to the chair,

The SECRETARY *pro tem.* (Mr. H. Wimhurst) read the circular convening the meeting, which he had issued with the co-operation of Mr. J. Barton, of Peterborough, and Mr. J. Carter, of Lincoln. They had, he said, received replies in favour of the formation of an Association from the following gentlemen:—Mr. W. Brown, of Brandon; Mr. Jackson, of Skegness; Mr. W. Palgrave Brown, of Southtown (Yarmouth); Mr. T. Greaves, of Melton Mowbray; Mr. A. J. Yorston, of Ely; Mr. W. H. Willis, of Yarmouth; Mr. A. H. Rose, of Wainfleet; Mr. J. Carter, of Lincoln; Mr. J. Barton, of Peterborough; Mr. W. J. Best, of St. Ives; Mr. B. H. Vores, of East Dereham; Mr. E. J. Brockway, of Oakham; Mr. C. Wright, of Saffron Walden; Mr. J. T. Jolliffe, of Ipswich; Mr. J. Kemp, of Haverhill; Mr. C. W. Grimwood, of Sudbury; Mr. F. Weller, of Southtown; Mr. W. H. Stout, of Boston; Mr. W. Wells, of Stamford; Mr. J. Heydon, of Mansfield; Mr. A. Mead, of Chelmsford; Mr. W. Barratt, of Grantham; Mr. H. Wimhurst, of Sleaford; Mr. C. Dixon, of Horncastle. There were in all 24 favourable replies. He had also received replies from other gentlemen, which he read. Some of the writers were undecided at present; a few were unfavourable to the proposal; others considered themselves situated in out-of-the-way places; while one or two intended waiting to "see what steps The Gas Institute would take in their present difficulty."

The CHAIRMAN remarked that, having heard the communications *pro* and *con.*, he presumed the matter they were to settle was whether or not there was to be an Association. They had heard what had been stated by those who were unfavourable to the project; and now he should be glad to hear what any gentleman present had to say with regard to it—whether or not it was necessary to establish an Association for the district. Personally, he considered it essentially necessary. He thought they must have all come to the conclusion that it was time something was started to get them out of the difficulty in which they were now placed. It had been a matter of surprise to him, and he had mentioned it more than once to his brother managers, that that part of the country—he would stand corrected if he was wrong—had only been once represented in what he might call the parent society, and that was by the gentleman who was at Grimsby, and whom Mr. Jowett succeeded.* This state of things he thought ought not to exist at all; it appeared to him to be rather one-sided—perhaps more one-sided than it should be. He should be glad to hear what gentleman present had to say as to the necessity of an Association being established.

Mr. W. J. BEST (St. Ives) asked what the "Eastern Counties" comprised.

The SECRETARY replied that, in sending out the circulars, he had included the whole of Lincolnshire, Cambridgeshire, Norfolk, Suffolk, parts of Essex and Huntingdonshire, Northamptonshire, and a little corner of Nottinghamshire. He also went up as far as Doncaster, as he did not know whether they might not get Mr. Bridge. Altogether, he sent out about 250 circulars.

Mr. J. BARTON (Peterborough) said he thought the time had arrived when they ought to form an Association for the Eastern Counties. When he first came to Peterborough, he felt very lonely indeed. He did not know his neighbours; and he did not suppose he had been to half-a-dozen works since then—some four years ago. When they had not an Association, they had not so much freedom; they could not go and inspect gas-works and make friends with the manager when they did not know him. They wanted a sort of introduction. If they had an Association, it would bring them together, and they could talk over affairs, compare notes, and exchange ideas. No doubt, as they went along, they would visit different works; and no matter how small the works might be, they would pick up something new. He thought when they became associated together in this way, it did a very great deal of good. They would have to arrange rules that day. They wanted to begin right; and if they began right, they would end right. He considered they had sufficient promise to warrant them in starting an Association.

Mr. BEST said that he had felt like Mr. Barton. When he first came into the Eastern Counties, he did not know many gentlemen. They had virtually to introduce themselves; and consequently he knew very few managers indeed in the Eastern Counties. At the same time, he failed to see any utility in joining The Gas Institute. He thought it was a long way to their meetings; while, with a local Association, they could go to some of the neighbouring towns, and compare notes with their fellow-managers. As far as he was concerned, he should say by all means have an Association for the Eastern Counties.

The SECRETARY remarked that, ten years ago, he felt himself in

a similar position to those who had already spoken. At that time he went to his friend Mr. Stout, and asked him whether they could not start an Association for the Eastern Counties, as he found them in all parts of the country. Mr. Stout, however, felt that at his time of life he could not embark in anything of the kind; and he referred him (the Secretary) to Mr. G. E. Stevenson, then of Peterborough. For some cause or other, he did not put himself in communication with Mr. Stevenson. He had felt a difficulty himself in not being able to meet his fellow-managers. If they would allow him, he should have pleasure in proposing that they form themselves into an Association comprising the districts he had already named. He thought they would be able to "paddle along," and in a short time get several more members. Mr. White, of Sherborne, told him that, when they started the South-West of England Association they only had 18 members; and in their (the Eastern Counties) case they had a larger guarantee. If they decided to start the Association, he had drawn up some rules for consideration. They were on the lines of the Midland Association rules, which he considered the best; excluding as they did a good deal of the outside world—such as traders and others. He had pleasure in proposing that an Association should be formed.

Mr. T. GREAVES (Melton Mowbray) seconded the proposition.

Mr. J. CARTER (Lincoln) considered that the amount of support which had already been promised to the projected Association was quite sufficient to warrant them in laying the foundation of what he hoped would be a considerable structure before very long. In his own mind, he did not agree with those who had any idea of withdrawing sympathy or support from what had been referred to as the parent body of gas managers. He thought there was plenty of room for one central body and for District Associations as well. It seemed to him very essential that they should continue their support to The Gas Institute, because it was important that there should be some thoroughly general representative body to speak with authority upon gas matters. At the same time, there were undoubtedly local circumstances which they felt more or less weighty, and which could be more thoroughly discussed by a body of gentlemen who themselves had to manage works situated within certain localities. They would find an Association extremely useful. They were all concerned in the management of the same business, and their deliberations and their visits to one another's works would, no doubt, do something to improve and perfect their education.

The proposition was then carried unanimously.

RULES.

The CHAIRMAN said that, having decided to form an Association, the Secretary would read the rules which he had drawn up.

The SECRETARY having read the rules he had prepared, they were discussed *seriatim*, and certain modifications were made. By Rule 1, the title of the Association is "The Eastern Counties Gas Managers' Association." Rule 2 says: "That this Association shall consist of engineers, managers, or secretaries exclusively engaged upon gas-works, in the service of gas companies or local authorities." Rule 5 declares that there shall not be less than four members of Committee. The tenth rule states that the meetings are to be held on the third Wednesday in March and the third Wednesday in September each year.

THE FIRST MEMBERS.

On the motion of Mr. F. WELLER (Southtown, Yarmouth), it was decided to enrol the gentlemen who had promised to support the Association—see list given above—as members. The name of Mr. F. A. Ward, of Amersham, was afterwards added.

ELECTION OF OFFICE-BEARERS.

Mr. GREAVES proposed that the Chairman that day should be elected the first President of the Association. He did not think they could have a better man.

Mr. BARTON thought that Mr. Barratt would make a good President, as he had had a great deal of experience.

The motion was carried *nem. con.*

The PRESIDENT briefly acknowledged the honour conferred upon him, and assured the members that he would do the best he could during his term of office.

On the motion of Mr. WIMHURST, seconded by Mr. CARTER, Mr. Barton was elected Vice-President.

Mr. CARTER moved the appointment of Mr. Wimhurst as Secretary and Treasurer.

Mr. HEYDON seconded the motion, which was carried.

Messrs. Best, Carter, Greaves, and Heydon were next elected to serve as the Committee; and Messrs. Weller and Yorston were appointed to the position of Auditors.

PLACE OF FIRST GENERAL MEETING.

The PRESIDENT suggested that Grantham should be the place of the first general meeting; and thereupon

The SECRETARY proposed that the first general meeting should be held, on the third Wednesday in March next, at Grantham.

Mr. WELLER seconded the proposition, which was carried.

PAPERS.

The SECRETARY observed that they would require one or two good papers for the meeting.

Mr. CARTER remarked that he very much favoured the idea advanced in the current issue of the JOURNAL OF GAS LIGHTING—that it should not be a *sine quâ non* that there should be papers. He considered that free-and-easy discussions upon matters of interest to all the members would do them more good than long papers.

* The speaker was not quite accurate in this statement; as we find, on reference to the Transactions of The Gas Institute, that Mr. G. Ernest Stevenson, formerly of Peterborough, was a member of the Council from 1881 to 1884.—Ed. J. G. L.

Mr. GREAVES concurred in Mr. Carter's remarks.

Mr. WIMHURST said that at all events they would have the Inaugural Address by the President at the next meeting.

VOTES OF THANKS.

Mr. CARTER moved that a vote of thanks be given to Mr. Wimhurst for the patient labour he had bestowed on the formation of the Association; as well as to the President for presiding, and to Mr. Barton.

Mr. YORSTON seconded the motion, which was heartily confirmed.

A vote of thanks having been passed to the Directors of the Peterborough Gas Company for the loan of the room, the proceedings were brought to a close.

Some of the members afterwards made a tour round the gas-works; being accompanied by Mr. Barton, who very courteously afforded all desired information.

SOUTH-WEST OF ENGLAND DISTRICT ASSOCIATION OF GAS MANAGERS.

THE HALF-YEARLY MEETING AT WESTON-SUPER-MARE.

We conclude to-day the extended report of the proceedings at the recent meeting of the South-West of England Association of Gas Managers. At the close of the discussion on Mr. Davis's paper, on "Naphthalene," the attention of the members was directed to the subject of

GASHOLDERS WITH SPIRAL GUIDES.

The PRESIDENT said that Mr. W. Gadd, of Manchester, had been kind enough to bring models of his patent system of gas-holder construction to show the members; and he would now ask that gentleman to explain them to the meeting.

Mr. GADD said that he would briefly describe his invention, beginning with the model of the single-lift holder. He would cause it to rise; and it would be seen that it was guided from the bottom entirely, there being no columns or girders above the ground. Yet it was held rigidly all round the bottom; each guide forming a holding point. Taking a hat, he might illustrate the ordinary way of supporting a holder with columns and framing, by supporting the hat on a stick from the centre of the crown inside; but in his system, the hat would be held down at points equidistant round the rim. The rollers played in lines preferably tangential; but this was in no wise a part of his system. They could be radial if desired. The guides in the tank, instead of being vertical, were disposed at an angle, forming a spiral, or quick thread of a screw. The angle might range from 45° to 60°; and anything between these limits was workable. Each roller formed a point of support; so that the holder was held in just as many places round the ring as there were guides. In the model before them there were six. Each roller formed a solid bearing; rendering the holder as stable as if it was resting on the floor. There was first a slight play on the bearings; and then the whole structure, holder and tank, could be turned bodily over as if one piece—the holder being gripped by the guides as in a vice. The holder formed a cantilever of the elbow kind—the height being the extent of one limb, and the diameter that of the other; so that if the wind pressure was concentrated at the top, the resisting leverage would still be much longer than the acting leverage. Another advantage obtained was that the pressure was rendered vertical. The shallower the holder, the more capable of resistance did it become; and in this respect it was just contrary to the ordinary system. He could make a very shallow frying-pan-like holder that would be perfectly stable. To illustrate the effect of unequal loading, such as an accumulation of snow on one part of the top, he would place a pile of lead weights near the circumference; and it would be seen that the holder rose and fell vertically, without tilting or straining. This showed that under any circumstances the strain on the guides was perfectly vertical. There could be no tilting, because the guides pointed in opposite directions on opposite sides of the tank; and therefore the rollers were gripped as between the blades of a pair of shears. He then showed the working of the three-lift model holder. The principle of his invention, he went on to say, was not affected by the manner in which the rollers and guides were designed; for instance, the rollers might be fixed on the tank, and the guides on the holder if preferred. The rollers could be built in the tank, in recesses of solid masonry, or the same might serve for the guides. In fact, the actual working arrangements might be modified in any practical way. The whole depended on the screw action. The three-lift holder might be compared to three screws, one inside the other. The interior framing, especially of telescopic holders, would have to be modified considerably to meet his system. The uprights could be made triangular in form, with base at the bottom of the curb, which would give more strength, and at the same time use no more weight of metal. The rollers could be double flanged, single flanged, or made in pairs without any flanges, having the guide between them.

Mr. WALTER FIDDES (Bristol) said he remembered that, when he was a boy his father made a model holder without columns and girders, guided by a central column, having a coarse screw on it for the rollers to work in. He asked if Mr. Gadd had any idea of the increased pressure that would be given by a holder on his system, as compared with the ordinary ones? Suppose, as was often the case, that 100,000 cubic feet of gas per hour were being delivered into the holder, and 300,000 feet per hour were passing out at the same time. Circumstances would differ from the ordinary working,

because there would be the effect of the lateral motion, and also the fact that the bottom must be heavier. The conversion of all wind pressure, &c., into a downward vertical strain would tend to influence the degree of pressure given by the holder. A heavy wind would increase the pressure. In connection with wind pressure, he would ask if the sucking or vacuum on the lee side, as well as the direct force on the windward side, had been taken into consideration. This was very considerable, and acting in the same direction practically increased the wind pressure. He had known the barometer on the lee side of a holder, during a strong wind, to stand 3-10ths of an inch lower than on the wind side. So the real wind pressure was really represented by that experienced on the windward side, *plus* the exhaust on the lee side. There was much difference of opinion with reference to wind pressure, the range over which it should be taken, &c.; and he thought that very few really understood the force of wind.

The PRESIDENT believed that the models before them to some extent represented the gasholders of the future, though all might not live to see them. Mr. Gadd had kindly attended the meeting at only a day's notice; and he had given a very interesting description of his invention.

Mr. GADD thought that the difference of pressure between a holder on his system and one on the ordinary plan would not be appreciable. Certainly in his case there was a slight lateral motion to overcome; but when the holder was floating in water like a ship, the force required for this would be very slight. A boat could be pulled along in still water with very small force, and twisted round with still less; and there was only the slight twisting action to be overcome in his holder. This might make it a trifle lighter in rising and a trifle heavier in falling; but he could say that it was so slight as to be quite inappreciable in the models, and he had tried one model 6 feet in diameter. It was simply a matter of the friction of the core of gas on the water and iron, and also of the part of the iron that was immersed on the water. As to the force of the wind, the Tay Bridge disaster showed our want of knowledge on the subject; but he had calculated on the data usually accepted by engineers. No doubt there was a violent wind action exerted over a small space at times. He thought his experiments showed that the degree of stability afforded by his plan was far greater than that of ordinary columns and guide-framing. He hoped before long to institute a series of tests, carried out to point of fracture, which would effectually determine this point. He would be quite satisfied to submit his system to any test of that kind, to see whether a greater force would be required to determine fracture than in the ordinary holder.

Mr. A. THOMAS (West Cowes) read the following description of

A PRESSURE-GAUGE HAVING NO FIXED JOINTS.

Pressure-gauges, as you are aware, although only small articles, are very important ones in gas-works. We frequently look at them as we pass from one part of the works to another, and become so used to seeing the water-line at about one height that I think if it altered only half an inch we should detect it. The pressure-gauge is the manager's friend, as it gives him timely warning of any coming stoppage. It is the "weather-glass" of a gas-works—the foreteller of coming trouble; and although the manager dreads the stoppage especially in winter, yet he is pleased to know of its approach before it actually takes place. What could we do without the pressure-gauge; and yet what appliance is there so frequently out of order. In saying this, I allude to gauges used for foul gas. How often has it occurred that, when some of the men have reported that something is wrong at the condenser or scrubber, or that gas is "blowing" at such a point, and we go to the gauge to find out what increase of pressure there is, we cannot even see the water in the glass, it being so foul. Then comes the scolding of the man whose place it is to keep the gauges clean; but all the scolding in the world does not rectify the matter. It must be cleaned; and how often the glasses are broken in doing so? Then a gauge has to be brought from some other part of the works, and valuable time is spent in removing and refixing. The question is asked, "Why is the gauge not kept clean?" and the real cause is found to be that the men dread the cleaning, as the glasses so frequently break with the least touch. I believe the men would prefer working up to their elbows in tar than have to clean some of the gauges in use at the present day; and the question with me has been, Why are gauges so complicated and delicately made?

The pressure-gauges of the present day that I have seen are altogether behind the times. Efforts have been made to beautify their outward appearance; but very little has been done to simplify them. Many of them are so tender that the least touch breaks them; and some will break even without a touch. So long as glass is fixed to brass or any other metal, just so long will the gauges be a trouble and a nuisance to both man and master.

Some years ago, when at Alton, I had a serious stoppage on the works; and when I went to the gauge to examine the pressure, the glass was so foul that I could not see the water-line, and trying to clean it in a hurry, as a matter of course, I broke it. It being necessary to know the pressure at once, I obtained a long bottle; and, putting a piece of glass tube into it, used it as a pressure-gauge, and from that I took my first idea of the gauge you have now before you. I do not for a moment claim that using two glass tubes, one inside the other is new, in whatever form they may be; but the general arrangement of the gauge, together with the rule being in the centre, acting for two gauges, is new—at least, the Patent Office admitted it was so, for they granted a patent for it. The gauge is made of glass tubes one inside the other. The brass mountings are steel

bronzed, or can be plated. The rule is made of boxwood; and the wooden back is polished.

I think with the ordinary gauges there are as many glasses broken by expansion and contraction of the metals surrounding them, as there are by the men when cleaning them; but in the case of the one before you, there is no possibility of breakage from undue expansion or contraction, for the reason that there are no *fixed joints*. What I have aimed at, in producing the present gauge, has been to do away with the trouble the ordinary gauges give in cleaning, and the risk of breakage when doing so. This I think you will admit, I have accomplished. Then, again, I have aimed at making a gauge that can be easily cleaned by an ordinary man or boy upon the works, and one that requires no skilled labour to fix. This I think you will also admit I have done.

The kind of gauge required for use in a gas-works where the pressure of crude gas has to be ascertained, is one that stands out bold and clear, and in which the water-line can be plainly seen. Such a gauge you have before you. We want a gauge that can be handed about without the fear of breakage—a something without the delicacy of the present style of gauge; so that, if it should be broken by accident, it can easily be repaired. Another thing about a gauge is that it should be so made that it can be taken from one place to another for use, if required, without any trouble in taking down or refixing; and with my gauge, all that it is necessary to do is to loosen the flexible tube, lift it from the nail, and it is ready for use in a moment where required.

While I am mentioning the fixing of gauges, I should like to say that when preparing the pipes for them, it is best to bring them up the walls on either side, and fix the tap below the gauge, and finish with a T 3 inches above the gauge, taking the supply from the side outlet, and fix a small tap upon the top of the T. If this is done, you will have a supply of air between the lower tap and the water in the glass tube, instead of crude gas; and if these taps are turned once a day, so as to allow the water to run level, the gauges will operate for a long time without getting discoloured, as you will have air only pressing upon the water. Nine inches of flexible tube is sufficient for each gauge.

Then another thing about a gauge is its cost. I am told that the price charged for 12-inch gauges and upwards is 1s. 6d. per inch. This, however, does not apply to gauges under 12 inches; for the one upon the table is a 6-inch, and cost, I believe, 14s. 6d. When you examine it, I do not think you will consider it is dear. It is a fair sample of an ordinary gauge, well made, and manufactured by a good firm; but there it is, both glasses are broken, and that without the help of man. It was broken by expansion or contraction while hanging in the office. I may say it broke itself; but, the one I bring before you to-day is not guilty of such tricks, for in it nothing is set fast, yet sufficiently fixed to produce a good, useful, and reliable gauge. As they are made chiefly for use where the pressure of crude gas has to be indicated, and where it is necessary to have both inlet and outlet before you, they are made in pairs, and commence at 12 inches, though shorter can be made if required for the inlet and outlet of governors, where excessive pressure is not likely to be met with.

The question of marking the rule has been raised. Some gentlemen think it should commence at the bottom, others that it should begin at the top. I have some made both ways, and have come to the conclusion that it would be better to mark them at the inches with the figures 10 to 20, and so on, from one end of the rule to the other. To have a zero upon a rule is a farce; for if you water the gauge to zero to-day, how long does it stay there. Which of us here can remember if the water was at zero when we left the works to attend this meeting, and which of us will complain if it is not at zero when we return. If the inch lines are carried across, and the half-inch lines half-way across, you then have all that is necessary for ordinary working purposes, without the tenths being upon the rule. I am now speaking of the manufacturing department. For "finished" gas, I admit that tenths are required; but as it costs nothing to put them on, perhaps it is as well to let them appear.

Discussion.

Mr. J. J. JERVIS (New Swindon) said he had pleasure in testifying to the efficiency of Mr. Thomas's gauge; having used one similar to it at his own works for the last six years. But he put india-rubber stoppers at the bottom of the large tubes in preference to making them solid. In this form the water was never blown out; and he would not think of returning to the old U-tube gauge. He exhibited the gauge referred to, which was made years ago from his own design.

Mr. H. G. CROWE (Wellington) remarked that he too had had a gauge on a similar principle, consisting of a glass tube immersed in an hydrometer glass, in use for some years. It was made by Mr. Lowe.

Mr. J. LOWE (Weymouth) thought that Mr. Thomas had put a new dress on a very old friend. He had known the principle for 25 years. About five years ago, he was induced to design a new gauge for his exhaustor-house; and he fell back on this plan, adopting with it the method of making a rubber joint for a steam-gauge. He had only used this arrangement (which he exhibited to the meeting) on the exhaustor. It consisted of an hydrometer glass, and an inner tube, kept in position by metal clamps, and graduated in inches. The gas supply was connected to this by the steam-joint above named. He preferred that the inner glass tube should be of the kind lately adopted for boilers; having an opaque half with a thin red line, as this clearly showed the water-level. The advantage of this form of gauge was that it showed the vacuum

as well as the pressure on the one tube. It could be very easily fixed, or made up to any length; and his was provided with an air-cock on the top. It was easily cleared; and he strongly recommended it as superior to the ordinary form of gauge.

Mr. S. W. DURKIN (Southampton) said he had tried one of Mr. Thomas's gauges, and used it in conjunction with one of the ordinary U-shape. With regard to the latter, he was occasionally troubled by the glass-tubes breaking. He connected up with rubber joints; and if the ordinary gauge had a plug at each end of the tube, there was not much difficulty in keeping it clean.

Mr. W. FIDDES (Bristol) said that this form of gauge was very old. One pattern, made of tin, would have been seen by many present. There was an outer cylinder 5 or 6 inches in diameter, and an inner tube; the gas being admitted to the space surrounding the tube. There was a float, having a wire pointer which extended above the inner tube, and worked in conjunction with an index, and also a little whistle which sounded when a certain pressure or exhaust was exceeded.

The PRESIDENT said that, while there was nothing new under the sun, Mr. Thomas had certainly shown an apparatus which was a great improvement on the ordinary form of gauge. One would hardly think a simple pressure-gauge could be the subject of so much discussion. With regard to the escape of gas in blowing, he observed that, in Mr. Lowe's arrangement, a very considerable quantity—enough to cause an explosion—could get out in this way. In the old gauge the tubes were smaller, so there would not be so much loss. Therefore the smaller the diameter of the centre tube, the better.

Mr. THOMAS was glad so much attention had been given to gauges, which had always seemed to him to be rather neglected. As to the principle, he had used it for the last 18 years or more; but having a little spare time lately, he devoted it to designing a simple and cheap form which could be easily cleaned and was not liable to be broken.

VOTES OF THANKS.

This being the last item on the programme of business,

Mr. LOWE said he was very pleased to propose a cordial vote of thanks to the gentlemen who had contributed to the proceedings at the meeting; and he would couple with the vote the name of Mr. Gadd, who had travelled a long distance in order to be present and explain his most interesting invention.

Mr. T. W. R. WHITE (Sherborne) seconded the proposition with pleasure, as the proceedings that day, he was sure, had furnished most useful information to all present. He had been pleased not only with the papers, but with the discussions, and the practical exposition given by Mr. Gadd, who also had greatly enhanced the interest attaching to his invention by the exhibition of models, which were so much more easy to understand than diagrams.

The proposition was unanimously carried.

Mr. GADD said that, as a visitor, he was pleased to respond on behalf of himself and those gentlemen who had contributed papers. It was a pleasure to him to be present; and he desired to acknowledge the courtesy and kindness he had received.

Mr. T. HARDICK (Salisbury) proposed a vote of thanks to the President for the energetic and able manner in which he had conducted the affairs of the Association during the past year.

Mr. CROWE seconded the proposition, which was agreed to.

The PRESIDENT, responding to the vote, said that he deeply felt the kindness of the Association, in the first place in putting him into the honourable position of President, and subsequently for the kind support extended to the very inefficient way in which he had carried out his duties. No one could exceed him in desiring the success of the Association; and he had endeavoured to secure it so far as his abilities would permit. If he had failed, it was not because he had not tried, and if he had succeeded, it was with the aid of the members generally. One duty he had to fulfil before sitting down, and that was to propose a very hearty vote of thanks to the Honorary Secretary and Treasurer, who was a right hand to the President. In fact, he thought the President was only a sort of ornamental head.

Mr. DURKIN seconded the motion, remarking that he was sure the Honorary Secretary had helped the Association on in every possible way.

The proposition having been carried,

Mr. HUMPHREYS replied, expressing his gratification at the kindly appreciation extended to his endeavours, and warning the members not to depend too much on their officers, but to bear in mind that the success of Associations such as these depended principally on the exertions of each member in attending the meetings whenever possible, in providing papers, taking part in the discussions, and suggesting subjects for consideration.

The meeting then terminated.

We learn from the *American Gaslight Journal* that a son of Mr. R. P. Spice, C.E., of Westminster, has been appointed Gas Inspector at Brooklyn, N.Y.

THE absconding Town Clerk of Salford (Mr. J. Graves) having been adjudicated bankrupt on the petition of a lady creditor for £818 6s., the first statutory meeting of creditors took place on the 25th ult., at the offices of the Official Receiver in Bankruptcy in Manchester. Proofs to the amount of £3805 had been lodged; among them being the £655 15s. 6d. claimed by the Corporation of Salford. A trustee was appointed, and a day fixed for the public examination. It was stated that if the debtor did not appear, a warrant would be applied for to arrest him.

THE LIGHT-GIVING POWER OF GERMAN CANDLES
OF VARIOUS MAKES.

A recent number of the *Journal des Usines a Gaz* contained the tabulated results of some experiments very carefully carried out by Herren A. Bunte and Scheithauer, with the object of ascertaining the illuminating power of various kinds of candles of German make. The figures given below show the conclusions arrived at by the experimenters, as far as regards stearine candles of the best quality (of which the characteristic is the perfect whiteness of the material), and paraffin candles of an opal-white colour. The heights

A DISTRICT SURVEYOR ON THE SUPPLY
OF WATER.

At the last Annual Meeting of the Association of Municipal and Sanitary Engineers and Surveyors, held in London, a paper on the subject of "Water Supply" was presented by Mr. W. SANTO CRIMP, Assoc. M. Inst. C.E., F.G.S. The following is an abstract of the communication:—

The author commenced by saying that pure water is an absolute necessity for the domestic uses of mankind; and where persons congregate together in large towns, the problem of its supply is frequently one difficult of solution. The quantity necessary for the various uses of the community is the first aspect of the question. During the seven years 1880-7, the average volume of water supplied per head per day in London was 31.32 gallons; the maximum rate of supply was 34.53 gallons; and the minimum, 28.12 gallons. The maximum rate of supply is in the months of July and August; whilst the minimum is during December, January, February, and March. It will be observed that the mean rate of supply is exceeded by very nearly 10 per cent. during the summer; whilst in winter the consumption is about 10 per cent. below the mean. To be accurate, the range between the minimum and maximum is, as nearly as possible, 22 per cent.

Whilst an ample supply should be furnished, waste should be strenuously guarded against, since waste of water is waste of money; and indeed during periods of prolonged drought, serious inconvenience, if not actual disaster, may result from a want of care in husbanding the stores of water available for the use of man. The following table will show what has already been done by the adoption of the very excellent system for detecting waste devised by Mr. Deacon:—

Table of Water Supply to Towns.

Town.	Daily Supply before Waste was stopped, in Gallons per Head.	Present Supply in Gallons per Head.
Atherton	no record	11.4
Abergavenny	42.0	17.2
Bath	36.0	12.0
Birkenhead	24.0	17.7
Bolton	32.5	14.8
Bradford	22.5	14.3
Carlisle	42.5	24.0
Chelsea Water Company	40.0	16.0
Chorley	not known	7.8

Norwich	40.0†	15.0§
Portsmouth	35.0†	18.3§
Southampton	60.0†	39.5§
Southwark and Vauxhall Water Com- pany	38.0†	22.2§
Stamford	24.0*	18.0†
Salisbury	50.0*	31.6†
Averages	38.6	20.13

* Intermittent. † Constant. § Exclusive of Trade.

The table shows that the proportion of waste is much higher than had been anticipated; and in towns of the ordinary class, 14 gallons only are used by each person daily, and allowing 6 gallons

of flame were measured by the Kruss method; and readings were taken every half minute during a quarter of an hour. The luminous intensity was ascertained by means of a Bunsen photometer; the unit of light being a Hefner-Altenack amyl-acetate lamp, equivalent, on an average, to the English candle. It will be seen from the figures how difficult it is to assign an exact light-giving value to a candle, of which the weight, hourly consumption, and luminous intensity vary (within very wide limits) with the make, and consequently render anything like effective comparison impossible.

for trade purposes, the total is 20 gallons per head per day. The consumption of water is not, as before pointed out, constant month by month. In the summer there is an increased demand on the mains for water for laying the dust on the streets, and for sewer-flushing, and other purposes. Then the water is not drawn from the mains at a regular rate throughout the whole 24 hours. During some of the night hours very little water is required, whilst in the forenoon water is constantly being drawn for domestic and other purposes. In laying down mains, therefore, not only must increase of population be provided for; but the main must be sufficient in size to admit of the maximum daily demand being satisfied. Disastrous results might follow on the breaking out of a fire during the hours of maximum draught, should the pressure not be maintained. If the mean yearly consumption be 20 gallons per head, 10 per cent. must be added for the summer requirements; making 22 gallons per head. Then this volume will be doubled during the hours of greatest consumption; hence the main must be capable of delivering about 44 gallons per head, if the generally approved system of "constant supply" be adopted.

The chief objections urged against the supply of water being "intermittent" are that the cisterns and other receptacles which are necessary for storing a day's supply, often become foul by reason of their position in the roof, under floors, or elsewhere, where they are difficult of access. Dr. Letheby stated, in giving evidence before the Rivers Pollution Commissioners, that the water drawn direct from the mains would be cooler and less liable to pollution, since the "receptacles of the poorer people were often close to privies, dirty cellars, &c." The chief objections to a constant supply (as recorded in the report of the Commissioners) were: (1) the leakage from fittings; (2) insufficiency of strength; (3) the greater consumption during the forenoon, rendering larger mains a necessity, and larger pumps where a service reservoir was not employed; (4) the greater draught in the forenoon reducing the pressure in the mains at the higher levels; (5) an accident to, or repair of a main, cutting off the house supply altogether, there being no house cisterns to keep up the supply. The Commissioners considered that a sufficient answer to these anticipated difficulties existed in the fact that at that date 72 towns had adopted the constant-supply system. Indeed, the better kind of fittings used with constant supplies had led to a great saving of water. The average supply per house per day of the 72 tabulated towns was 134.4 gallons, or about 24.4 gallons per head; whilst in the case of 24 towns—including London—supplied intermittently, 204 gallons were supplied to each house per day, or 37 gallons per head.

Turning to the general sources of water supply, the author said that the primary source is rain, and then went on to speak of the various modes of collecting it. The water yielded by gathering-grounds is frequently of a peaty colour, owing to the colouring matters in the dead plants being dissolved out just as ordinary water may be discoloured by placing in it a wisp of hay. The rains following prolonged droughts are specially affected; and means are sometimes adopted for the separation of highly coloured streams from the general supply. The vegetable organic matter is lessened by exposure to atmospheric oxidation in lakes and reservoirs; and, therefore, the larger these are in proportion to the water drawn from them, the purer will the water become. It has sometimes occurred that the soft waters collected in lakes and reservoirs possess the property of dissolving lead from the services by which it is taken from the mains into the houses. Loch Katrine water is especially active in this respect. The question was very fully examined by the Rivers Pollution Commissioners; and they arrived at the conclusion that, in order to secure immunity from attacks upon lead, it is necessary that these soft waters should contain a certain proportion of phosphate of lime. They also stated in their report that new untarnished lead pipes are acted upon much more violently than those which have been in use for some time; a protecting film soon being deposited upon

those surfaces in contact with the water. Pipes lined with tin in such a manner that the tin does not form an alloy with the lead, but remains pure, are not affected by the attacks of soft water. In the case of shallow well waters, the action upon lead and galvanized iron is in some instances of a continuous and violent kind. Such a case was that of the Oakfield well at Wimbledon, mentioned in the report referred to, in which an analysis of the water showed it to be deficient in carbonic acid, and wholly free from phosphates.

Returning to the "gathering-ground," the water falling as rain soon forms little streams. These unite as their courses tend to the lower levels, until low down the valley, their aggregation is seen in the roaring torrent, or the placidly flowing river. At what point in the valley should the water be intercepted? If there is a natural lake of sufficient size, its waters may be abstracted, or its area may be added to by means of an embankment or wall, should that course be necessary. If no lake exists, a natural one must be formed by means of a wall or an embankment; but in selecting the point for its construction, an accurate knowledge of the geological strata of the immediate locality must be ascertained. If the strata are of a rocky nature, with fissures, it may be necessary to carry the retaining medium to a very considerable depth, in order to prevent the escape of the water, and the possible destruction of the embankment. The bottom of the reservoir must also be made water-tight so far as is practicable; and very great care must be taken in the design of the outlet arrangements. In short, as the most disastrous results to life and property might follow the failure of a reservoir dam—as at Sheffield in 1864—it is impossible to exercise too much care in all the details affecting its design and construction.

Possibly the greatest difficulty in connection with proposed water-works of the kind under discussion is that of ascertaining the volume of water that will be yielded by a given gathering-ground, or watershed. If the surface is largely composed of steep, rocky, impervious formations, the water will be rapidly delivered into the valleys, with the retention by the surfaces of a comparatively small quantity. Should the area, on the other hand, be of a flat character, with much vegetation, large quantities of water will be retained by the plants, particularly in the case of thick deposits of peat; the water remaining in the pores of which, and on the various surfaces, evaporates on the cessation of the wet weather. Some of the water might also be lost by percolation, should porous strata be present. In the case of great chalk formations, it is rarely that any water flows off the surface. Dr. Dalton, who has given many years of study to the question of the volumes of water available for water supply proportionately to the rainfall of this country, states that the amount is about one-third of the total rainfall. At Loch Katrine in 1854, the rainfall for the year was 103 inches, four-fifths of which were discharged by the loch; one-fifth being lost by evaporation, percolation, and absorption. It will, however, be much more correct to assume that the losses through the various causes will be certain in amount yearly, than to calculate that it will be proportional to the rainfall. Dr. Pole estimated that the losses would vary from 12 to 18 inches in depth per annum, accordingly as the gathering-ground might be of steep impermeable rock, or of flatter permeable formations. In calculating the size necessary for a storage reservoir, the mean annual rainfall of the district in which it is to be situated must be ascertained; and as the yearly fluctuations of the rainfall are very considerable, provision must be made for impounding a supply sufficient for the wants of the community during periods of drought. Dr. Pole, in his work on "Water Supply," stated that, in the judgment of experienced practitioners, 150 days' storage should be provided in wet districts, and 200 days in dry. In very wet districts the storage to be provided might be less.

Objections have been frequently urged to the abstraction of raw river water for domestic supplies, in consequence of the fouling of the streams by sewage and by other matters. As diphtheria and typhoid fever are most readily communicated by means of water, every endeavour should be made to obtain a supply free from suspicion. Five of the London Water Companies take their supplies direct from the Thames; and, with the great improvements in the construction of filters during recent years, experience shows that such water may be rendered wholesome and fit for domestic purposes. Wimbledon is supplied by two of the Companies, and for years the death-rate has averaged about 12 per 1000; there being no wide fluctuations such as are indicative of defective sanitary conditions.

Referring to the filtration of water, the author said that the rate of filtration, to be effective, should not exceed $2\frac{1}{2}$ gallons per square foot of filter per hour, or 540 gallons per square yard per 24 hours. Subsidence of the suspended matters was desirable before the water was admitted to the filters, in order to prevent the pores of the filters being choked. The filters must be kept in a cleanly condition; the top inch or so of sand being periodically removed and replaced by clean sand. As the London water supply for the year 1886 averaged 80.47 gallons per head per day, each square foot of filter served for the filtration of the water required for two persons, or one acre would be necessary for 87,000 persons. As, however, portions of the filtering area were always undergoing cleaning operations, the area of filter actually provided was necessarily in excess of the estimated amount.

Passing on to consider the quality of water, the author said it must be remembered that water procured from wells was simply that portion of the rainfall which passed downwards through porous strata, and was stored in the crevices and pores of the various formations suitable for its reception. When the strata

passed through by the water were of limestone, a portion was dissolved; and waters derived from these formations were said to be hard—in other words, they contained various salts in solution, in consequence of which they had a harsh feeling when used for personal ablution, and much soap was destroyed in artificially softening them. He went on to explain that water is said to be "temporarily" hard, or "permanently" hard, according as the water may contain the bicarbonates of lime and magnesia, or the sulphates of the same minerals. The term "temporary" hardness is used because the water so hardened may be softened by boiling; the salts being decomposed into free carbonic acid and the carbonates of lime and magnesia, which latter are sparingly soluble. When water cannot be softened in this way—as when it is hardened by the sulphates of lime or magnesia—it is said to be "permanently" hard. All hard waters may be softened by distillation, as the salts will not pass over with the vapour; but water so softened has a flat, unpalatable taste, owing principally to the absence of carbonic acid gas, and to the presence of volatile organic matter. The remedy is to filter the distilled water through animal charcoal; but the process is a costly one. Water is commonly softened by boiling, and the separation of the hardening salts may be effected by constant ebullition for half an hour. The salts which are present as bicarbonates are decomposed into insoluble, or sparingly soluble, carbonates of lime, magnesia, or iron; carbonic acid gas being expelled by the process of boiling. Water so softened is frequently muddy, in consequence of the dissolved solids becoming changed into visible suspended matters. In order to raise the temperature of 1000 gallons of water to the boiling point, and to maintain it in this condition for half an hour, $2\frac{1}{2}$ cwt. of coal would be required. This method of softening water is therefore an expensive one. The process of softening water by means of lime, as devised by Dr. Clark, is the cheapest yet known, and is in extensive operation at many water-works situated on the great limestone formations. The process, however, is only applicable to those waters which owe their hardness to the carbonates of lime and magnesia; that is, to waters which are said to be temporarily hard. The chemical action is a simple one. The chalk or other hardening salt exists in water as a bicarbonate, which is soluble; lime is added to the water to be softened, and, combining with a portion of the free carbonic acid, forms carbonate of lime; the bicarbonate present in the water is decomposed—into carbonate also—by the withdrawal of a portion of the carbonic acid, and the water so treated becomes turbid from the production of nearly insoluble salts. Settling-tanks are provided in which the suspended solids may subside; and the softened water, as then distributed for use, contains only about 4° of hardness. Mechanical filters, as in the "Porter-Clark" process, have more recently been introduced for the purpose of separating the suspended solids produced; thus rendering unnecessary the settling-tanks at first used. Chalk water with $17\frac{1}{2}$ ° of hardness would contain 1 lb. of chalk in 400 gallons. In order to precipitate the chalk, 9 oz. of lime, dissolved in 40 gallons of water, would be necessary. The lime would combine with the free carbonic acid to produce 1 lb. of chalk also; and the precipitate would be 2 lbs. of chalk, assuming the chemical action to be complete. As 1 cwt. of lime only costs 8d., it is to the great benefit of the community that hard waters should be softened by means of this material at the works.

With regard to the internal distribution of water after its collection and filtration, the author thought this question was one which did not require to be considered at very great length. The sizes of the various subsidiary mains would, he said, be regulated by the probable demand. In his district, the smallest branch-mains used are 3 inches in diameter; this size being considered sufficient for the greatest demand likely to arise in the case of a fire breaking out in a side street. The mains should be jointed with lead only, if turned and bored joints were not used; as the use of tow or gaskin had led to the pollution of the water supply. This was notably the case in a main laid by the Southwark and Vauxhall Company in 1869. The mains must be furnished with the necessary valves, hydrants, and means for washing out. Pumping machinery should be provided in duplicate, in order to allow for a possible breakdown, should it be necessary to pump the required water. The service reservoir is a necessary adjunct of a water supply scheme, in order to regulate the fluctuations of the demand, and to contain a store for sudden emergencies. According to Dr. Pole, such reservoirs should contain from one to one and a half day's supply, and should be covered, in order to exclude dirt, and diminish the risks of pollution.

The author closed his communication with a few remarks on the prevention of waste; dwelling on the importance of the house fittings being of the best quality and type, and so arranged as to prevent contamination of the main supply. He pointed out that the regulations made under the Metropolis Water Act, 1871, were very valuable from a sanitary point of view; and in the hope that they might be of service to members of the Association, he included them in his paper.

THE works of the Eye Gas Company have been let to Mr. T. Faulkner, formerly Manager of the Stowmarket Gas-Works, who will take possession on the 1st prox.

MR. E. D. WALKER, the present Chairman of the Gas Committee of the Darlington Corporation, who is retiring from the representation of one of the wards, has announced his decision to leave the Council at the end of the present month.

Register of Patents.

GAS-LAMPS.—Cole, H. W. and A. F., of Stourport. No. 11,669; Aug. 27, 1887. [8d.]

This invention relates to improvements in the construction of the air passages of regenerative gas-lamps, so as to render them applicable for ventilating and lighting purposes generally.

In figs. 1 and 2, the gas is arranged to pass down the pipe A to the burner B; and, issuing out through the holes of the burner, forms a round flame. The heat and products of combustion from the flame, on passing up the combustion chamber C to the chimney D, surround and impinge on the shoulders and walls of the hot-air chamber or box E, and also on the shoulders and around the hot-air passages E1; thereby highly heating the same. The air to supply the top side of the flame enters through the passages E1 round the circular or tangential passages in the chamber or box E, and down the centre tube F, to the top of the flame. The surface so exposed to the action of the flame highly heats the air on its course from the passages E1 to the burner B. Air is supplied to the under side of the flame through the air-holes G, in the usual manner; the air descending the sides of the glass H, and then rising heated to the flame. By the passages E being circular or tangential, a whirling motion is imparted to the heated air passing there-through; and the heated air being properly regulated, ensures practically perfect combustion, and a steady and brilliant light. The gas is lighted by moving the catch I, and opening the ring L, which holds the glass in position; or else by opening a plug or cover N, as shown in the bottom of the glass at M.

The lamp in figs. 1 and 2 is shown as having two circular or tangential hot-air passages; but the number and size of such passages will be varied according to the size of the lamp and the amount of heating surface required. For instance, in the lamp fig. 3, three passages are employed.

The centre tube F in fig. 2 is shown the same diameter throughout; but it may be made to partly taper, as in fig. 4 at F1, or made taper its whole length.

In the modification fig. 4, a hot-air chamber or box E is used, which is heated in the same manner as the lamp in figs. 1, 2, and 3; and it is supplied with air through the passages E1 into the chamber or box E. The air, as it is being heated, takes a circular course, in the direction of the arrows, through the chamber or box E, down the centre tube F, to the burner B. The tube F is by preference tapered as shown at F1; and a few holes can be drilled at E2, if desirable, to admit more air to the tube F, and also to prevent dust accumulating. Air passes through the holes G to supply the underside of the flame with air; and the heat from the flame passes up the combustion chamber C to the chimney D. The number and size of the air passages E1, supplying the chamber or box E with air, will be varied according to the size of the lamp.

GAS-ENGINES.—Day, C., of Sheffield. No. 13,916; Oct. 13, 1887. [8d.]

This invention relates to improvements in gas-engines of single or twin-cylinder type, using a practically homogeneous mixture of air and gas, and working on the four-cycle principle.

It has for its object, first, to enable the residual gases of combustion to be wholly swept out of the working cylinder, by a "scavenger" charge of pure air, whilst the working piston is making its exhaust stroke. For this purpose, there is combined with the working cylinder, an air pump working in such manner that the delivery of air therefrom to the working cylinder takes place coincidently with the discharge of waste gases during the exhaust stroke of the working piston; the air being delivered from the pump to the cylinder directly in front of the working piston in such a direction as to force out of the working cylinder as much as possible of the residual gases of the previous explosion, so that there shall only remain in the cylinder pure air to be mixed with the next incoming charge of gas and air. To this end the air-pump cylinder is in connection with the working cylinder through an ordinary lift discharge-valve which may either be lightly loaded and open automatically, or be worked by suitable gear. The scavenger charge of air is forced, under slight pressure, into the working cylinder, preferably through the working piston itself, which has for that purpose a passage through its back end in communication (by a longitudinal groove in its side) with the port leading from the air-pump discharge-valve. By this means, the gases of combustion will be expelled through the exhaust-valve of the working cylinder, partly by the working piston and partly by the scavenger charge, which is forced into the working cylinder during the exhaust stroke in such a way as to carry before it,

and expel from the cylinder, the residual gases from the previous explosion. By this means the combustion chamber will contain at the end of the exhaust-stroke nearly pure air instead of gases of combustion. To ensure the intimate and homogeneous mixture of the inhaled charge of combustible gas and air with the air remaining in the combustion chamber from the previous scavenger charge, the inlet port of the combustion chamber is covered with a fine rose, through which the charge passes (at a high velocity) in fine jets directed towards different parts of the combustion chamber; the resulting explosive mixture being thus practically homogeneous.

The invention has, secondly, for its object to regulate the speed of the engine in which a scavenger charge of pure air is used. As the combustion chamber contains only pure (or nearly pure) air at the commencement of the inhaling stroke, the inhaled combustible charge must be more than usually rich in gas in order that the gas and air—including the residual scavenger charge—may be present in the proper proportions in the cylinder to constitute an efficient firing mixture. When the maximum power of the engine is required, the explosive mixture is relatively rich; and in order that the speed may be regulated within certain limits, the engine is made to automatically reduce the quantity of gas, or of air and gas, inhaled. Before, however, the mixture in the cylinder becomes so impoverished that it will not fire with good effect, the engine is made to cut off the gas supply entirely; and the engine will then, without loss, miss fire by the exhaustion of unexploded gas, until the speed of the engine is reduced sufficiently, whereupon the normal working will be resumed.

SOFTENING AND PURIFYING WATER.—Porter, J. H. and G., of Queen Victoria Street, London, and Porter, J., of Leicester. No. 13,943; Oct. 14, 1887. [8d.]

This invention is designed primarily to facilitate the adoption of Clark's process for the softening and purification of water for the supply of towns, in the same way as at present available on a small scale.

In carrying out the process for the water supply of towns, such as Canterbury, Caterham, and other places, large reservoirs or tanks (each capable of containing one day's consumption) are necessary, by reason of the many hours required for the clearing of the water by the precipitation and subsidence of the finely-divided chalk and other matters produced in the process. In lieu of such large duplicate reservoirs or tanks, the patentees propose to employ one of smaller dimensions, or utilize a portion only of a large storage reservoir, and expedite and perfect the clearing of the chalky water by causing it to pass into a series of filtering partitions extending across the reservoir or tank. To construct these filtering partitions in an economical manner, and to admit of the convenient cleansing of the filtering surfaces and of their renewal when necessary, a series of wires or rods under tensile strain are stretched across the reservoir or tank, with upright supports at intervals to maintain the wires or rods in a horizontal position. On one or both sides of the skeleton thus provided, there is placed a backing of matting or fabric, metallic or textile; and this is secured to the wires or rods with a covering of filtering cloth arranged for easy removal when desired. In this way the inner fabric serves to convey through its interstices or channels, or by what may be called capillary action or attraction, the clear water that, having deposited the chalk or other matter in suspension upon the surfaces of the outer cloths, has passed through them to the inner sides. The lower edges of the inner matting are confined between the lips or flanges of an outlet channel or pipe; and, where the top of the partition is below the surface of the water in the reservoir or tank, the filtration may be expedited by connecting the outlet-pipe with the suction of a pump.

LIQUID-METERS.—Tylor, J. J., of Newgate Street, London. No. 14,652; Oct. 27, 1887. [8d.]

This invention relates to inferential liquid-meters; and has special reference to the kind of meter described in patent No. 10,443 of 1885. The object of the invention is to provide means whereby the range of correct registration of meters of this kind is increased beyond what can be obtained by any form of brake heretofore used, and to increase the sensitiveness of the meters themselves. Illustrations are given of two vertical sectional elevations of meter cases constructed in accordance with the present improvements.

The invention consists, firstly, in forming the internal surface of the circular chamber D, in which the registering fan or wheel F revolves, with a series of alternate projections P, and hollows or grooves Q, which retain the outer layer of water in the fan chamber D, in such a manner that it has a retarding or brake-like effect upon the revolving wheel or fan F, whereby the latter is prevented from moving at a speed which is inconsistent with the quantity of water passing through the meter. The projections and hollows may either be formed on the cylindrical sides of the chamber D, as shown at P' Q', or on the bottom, as at P1 Q1, or on both sides and bottom; and they may be placed in a vertical or radial direction, or at any suitable angle with reference to the direction of the stream of water. Meters constructed in this way enable the current of liquid passing through the meter to act centrally upon the measuring fan, whereby the side action, and consequent wear and tear on the toe-pieces, occurring the meters with oval cases having only two brake surfaces is obviated; the brake action due to the projections and hollows being equal at every point of the circumference. The measuring fans of meters so constructed may also be run much faster, it is claimed, and with less noise than those of meters as ordinarily made; and this

increased speed of the measuring fan gives a greater range of correct registration.

The invention consists, secondly, in forming the parts of the registering fan or wheel F near the axis, so that each part slopes alternately in an opposite direction. In this way the tendency of the fan to be raised off its toe-piece, or to be pressed down thereon by reason of all the parts of the blades near the axis being sloped in one direction, is obviated.

APPLICATIONS FOR LETTERS PATENT.

13,696.—SCOTT, C. H., "Improvements in brick-kilns fired by gas." Sept. 22.

PATENTS WHICH HAVE BECOME VOID.

[AFTER THE FOURTH YEAR.]

9033.—CAINK, T.—"Lighting gas, &c."

9065.—SALISBURY, S. C., "Making of gas."

9072.—BOYD, R. W., "Gas or oil stove."

9084.—BOULT, A. J. (Hanlon), "Illuminating gas."

THE PUBLIC LIGHTING OF BROMLEY.—At a meeting of the Bromley Local Board last Thursday, it was decided to erect twelve additional lamps, to be lighted with oil, as an experiment.

THE PRICE OF GAS IN THE MANCHESTER OUT-DISTRICTS.—At the meeting of the Newton Heath Local Board of Health last Thursday, the Chairman (Mr. J. M. Elliott) reported that, as representing the Board, he attended a meeting of Local Authorities held at the Grand Hotel, Manchester, on the previous day, as to the price of gas supplied by Manchester to districts beyond the city. It was stated that the Manchester Corporation last year made a profit of £70,727 out of the supply of gas, to which the out-districts contributed £26,550. The whole of the £70,727 went to Manchester, and no portion was returned to the out-townships. It was contended that a fair and equitable charge would be 2s. 3d. per 1000 cubic feet in Manchester, and 2s. 6d. outside; and at these rates there would remain a considerable profit in favour of Manchester. The meeting decided to wait upon the Corporation by deputation, with the view of arriving at a mutual and satisfactory arrangement.

NORTHERN COAL TRADE.—The northern coal trade continues active, except in the steam coal branch. At this season of the year, steam coal usually begins to show signs of falling off in the demand. At present about 7s. 6d. is the current price for best qualities. In gas coal the inquiry is growing, and many of the largest collieries find that the amount needed is more than at this season of any previous year. The demand for gas for fuel and power is being extended; and this, coupled with the increased quantity needed for lighting purposes, causes an additional inquiry for gas coal as a whole. There was no change in the price last week. Manufacturing coal is very firm, and most of the contracts which expire are renewed at advances varying from 3d. to 6d. per ton, according to the lowness or otherwise of the price in the current contracts. The bunkering coal trade is stronger; but prices do not rise for this class of coal as for manufacturing and gas coal. The demand for coke of all classes increases, especially for blast-furnaces and cement works.

ALLIANCE AND DUBLIN CONSUMERS' GAS COMPANY.—According to the accounts presented to the shareholders of the above Company at their half-yearly meeting last Saturday, the total income for the six months ending June 30 last, including the balance of interest on the invested funds, amounted to £119,084, against an expenditure, including debenture interest, of £83,250; leaving a net profit of £35,834. Adding to this sum the balance of £1325 brought forward, there was £37,159 available for division. The Directors recommended dividends of 10½ and 7½ per cent. per annum on the respective shares, payment of which would absorb £35,725; leaving a balance of £2434 to be carried forward. Compared with the corresponding period of 1887, there was an increase of £1762 in the receipts for gas, and of £1981 in those for tar and ammoniacal liquor; but the value of coke having considerably decreased, there was a loss of £1476 under this head. The amount of coal carbonized during the six months was 58,431 tons; and the quantity of gas made was 610,960,000 cubic feet. Of which 532,688,000 cubic feet were sold. The residuals were: Coke, 70,366 chaldrons; breeze, 1954 chaldrons; tar, 593,946 gallons; ammoniacal liquor, 1,493,308 gallons. Of the tar, 12,236 gallons were utilized in the manufacture of gas.

THE TYNEMOUTH CORPORATION AND ELECTRIC LIGHTING.—At a recent meeting of the Watch Committee of the Tynemouth Town Council, letters on the subject of electric lighting were read from the Local Government Board, the Clerk to the Barnet Local Board, and several of the electric lighting companies. It was resolved that the matter should be left in the hands of the Watch Committee, with the addition of two members of the Council, for them to report to the Council; the Borough Engineer in the meantime to prepare a plan showing the public buildings in the vicinity of the market which it had been suggested should be lighted by the electric light. A special meeting of the Town Council has been convened by the Mayor (Mr. G. Dodds) for Thursday next, for the purpose of considering, and, if so ordered, of adopting a resolution approving of the intention of the Council, as the Local Authority under the Electric Lighting Act, to apply to the Board of Trade for a Provisional Order to authorize the supply of electricity for public and private purposes within their district, and also to consider the terms of the Order. The question of extending the electric light in the borough is one that is now engrossing public attention, and the outcome of the special meeting of the Council is awaited with considerable interest.

TORQUAY GAS COMPANY.—At the half-yearly meeting of this Company held last Thursday, at the Company's new offices, Torquay, under the presidency of Mr. W. H. Kitson, the Chairman, it was stated that the receipts for the half year amounted to £11,189, and the expenditure to £7155; leaving a balance of £4034. The Chairman having welcomed the shareholders to the Company's new premises, alluded to the accounts; remarking that the Company was in a much better position now than it had been for some time—the balance in hand after paying the dividend being £1081, as against a few shillings. There was an increase of nearly £1000 in the sale of gas. He then spoke in defence of the Directors on the question of allowing a discount to the Local Board on the gas consumed for public lighting—a matter which had been the subject of some correspondence; and showed, from statistics, that in the majority of towns throughout the country the authorities were charged at the same rate as the private consumers. He also proved that although the amount allowed to be charged by Act of Parliament was 5s. 6d. per 1000 cubic feet, the Directors had always kept the price as low as possible—3s. 6d. being the present charge. He moved the payment of dividends at the rates of 10 and 7 per cent. per annum; and the proposal was adopted.

Correspondence.

MODIFICATION OF HARCOURT'S COLOUR TEST.—GAS ANALYSIS.

SIR,—I have read Mr. Leicester Greville's article on the above subject published in this week's JOURNAL.

Shortly he remarks: (1) That there is no connection between my apparatus and Mr. Harcourt's. (2) My methods are simply those already well known to chemists. (3) The determination of ammonia by means of passing a known quantity of gas through test acid is in daily use as the Referees' test; that the direct passage of the gas through the solution makes this a rough test, which is only practically available where the proportion of ammonia is comparatively large. (4) The estimation of carbonic acid by means of barium hydrate is a well-known method. (5) The process for the estimation of sulphuretted hydrogen is open to very grave objection, owing to the well-known solubility of the gas in aqueous solutions. (6) With regard to temperature and pressure corrections in determinations of this character, he must confess to have as a rule ignored them, as the modes of operation are not, in his opinion, sufficiently correct to necessitate such refinement, and Mr. Hicks obtained 6½ inches exhaust from using two tubes, which is really unnecessary.

In reply, I may say: (1) That the platinized pumice bulb and the test-glasses are the same as used by Mr. Harcourt; but the methods of using them are certainly not like his. Does Mr. Greville really think that an unskilled person can more easily judge the colour of solutions to be of the same tint, or discriminate between a strong contrast such as red and blue or a colourless liquid and a bright red liquid? (2) The test solutions are not in general use, they being gas normal solutions; and the method of using these solutions in the test-glasses is new, as far as I am aware. (3) The first part of this is answered by No. 2; and as to the direct passage of the gas through the solution in fine bubbles, I am of opinion that it must be better than passing the gas through beads wetted with the acid. (4) Mr. Greville makes no objection to the test for carbonic acid. (5) I must distinctly state that the water in which the acetate of lead is dissolved has but little retaining effect on the sulphuretted hydrogen, to prove which I have made the following experiment:—I placed in the test-glass B (which is employed for sulphuretted hydrogen) an amount of distilled water equal to the acetate of lead solution usually used (about 70 cc.). I then connected it to the inlet of the purifiers, and to the aspirator; but before I had time to open the tap of the aspirator, two or three small bubbles of gas passed through the water (due to the pressure in the main), and the lead paper was immediately discoloured. (6) Mr. Greville must please himself about these corrections; but I might state that the variations due to temperature and pressure are greater than those due to the use of aqueous solutions. I have tried a great many experiments with this apparatus, and have found that two vessels are necessary. I have worked with Mr. Sheard's apparatus for carbonic acid (which I consider a most perfect test) against mine with one vessel and with two. With one the result was nearly a third less than with Mr. Sheard's; but with two glasses both results were the same. I might add that the current of gas should be slow, especially with the sulphuretted hydrogen test.

The last paragraph of Mr. Greville's article may be taken as the key to the whole. He says in effect that my apparatus does not come up to his modification of Harcourt's colour test? This, however, is only a matter of opinion from a not unprejudiced source, which each reader of the JOURNAL will better decide for himself.

In reply to Mr. Whieldon's letter, also published in this week's JOURNAL, I may say that, now he has explained what a "slight under-pressure" means, this can be done by lowering the water in the neck. The 0.3 per cent. of ammonia mentioned in the article was, as stated, an assumed figure taken for illustration, and not as a positive; hence Mr. Whieldon's mistake.

Further, he remarks that the effect of surface contact with the water is to vitiate the tests; and, again, he does not see the use of corrections for temperature and pressure. This is very fast and loose. If he really thinks corrections are needed for surface contact with water, how much more so for temperature and pressure, where the range of error is greater and more uncertain? While for water contact, if any error exists, it can be correctly ascertained and allowed for; the maximum quantity of gases absorbed by water having been already stated by Mr. Whieldon.

In conclusion, I may say that the results obtained by my bottle have been carefully checked by those from Mr. Wanklyn's; and in every case they have agreed. This does not bear out Mr. Whieldon's opinion that the results by my apparatus would be practically valueless.

I may say with regard to the cost of the apparatus, which Mr. Whieldon says is of no consequence, that to the Commercial Gas Company this may be so, as doubtless they can afford, and may possess whatever they desire without reference to cost; but while this may be of no very great consequence to them, to private individuals or small companies, who are compelled to study economy in small matters, I think it is of the utmost importance.

Ramsgate, Sept. 28, 1888.

WILLIAM G. HICKS.

THE PUBLIC LIGHTING OF EXETER.—The Exeter Gas Company, replying to the Town Council's request to determine the existing contract for lighting the public lamps at Michaelmas, said the Directors were willing to have a yearly contract as heretofore, or would enter into a contract for seven years for the whole of the lighting area of the city, at 2s. 9d. per 1000 cubic feet, provided the Council would use lamps of a higher power for the principal streets; the basis of the old agreement to remain in other respects the same as before. It was mentioned that a communication had been received from the Defries Safety Lamp Company, informing the Council that they were prepared to tender for supplying as many of the Company's lamps as might be required, including all labour, for £2 12s. per lamp per annum; the lamps to be alight from sunset to sunrise. The Surveyor was requested to obtain a sample lamp, and any other lamp he might consider suitable, and report to the Committee. After some discussion, it was decided to accept a contract with the Gas Company for another year.

Miscellaneous News.

COMMERCIAL GAS COMPANY.

The following is the report of the Directors of this Company, which, with the accounts for the half year ending June 30 last (the principal portions of which are given below), will be presented at the ordinary general meeting of the proprietors to be held on Friday next:—

The revenue account shows a net profit for the half year of £52,166 9s. ; making, with £1044 1s. 3d. received for interest, £53,210 10s. 3d. This, added to the amount brought forward from previous half years, makes £97,293 3s. 9d. Deducting therefrom £2727 15s. 4d. for interest on debenture stock, there remains standing to the credit of the net revenue account a balance of £94,565 8s. 5d., of which, having regard to the sliding scale and the price of gas charged during the half year, £44,800 is available for dividend. The Directors recommend the payment of dividends at the

rates of £13 15s. per cent. per annum upon the old stock of the Company, and of £10 15s. per cent. per annum upon the new stock, both less income-tax. The balance of the net revenue, £49,765 8s. 5d., will be carried forward to the next half year.

The accounts accompanying the report consist of the usual statements ; those relating to the capital of the undertaking (Nos. 1 to 3) showing only one change as compared with the preceding half year. The statement of capital stock (No. 1) stands as it did on Dec. 31 last—viz., £680,000 paid up, out of a total of £830,000 authorized. The statement of loan capital (No. 2) also stands as before—viz., £121,234 borrowed, out of £300,000 authorized. The total capital called up at the end of the past half year was, therefore, £801,234. The capital account (No. 3) shows a total expenditure of £808,098 19s. 1d., of which £2037 19s. 1d. was laid out on new works, mains and services, meters, and stoves in the six months covered by the report. The amount by which this account has been over-drawn has, therefore, been increased from £4826, on Dec. 31 last, to £6864 19s. 1d. The remaining statements are as follows:—

No. 4.—REVENUE ACCOUNT.

To Manufacture of gas—	
Coals, including dues, carriage, unloading, and trimming (see account No. 8)	£57,694 12 7
Salaries of Engineers, Superintendents, and other Officers at works	1,993 9 8
Wages (carbonizing)	13,498 17 8
Purification, including £1293 2s. 9d. for labour	2,919 0 9
Repairs and maintenance of plant and works, materials and labour (less £246 0s. 10d. received for old materials)	9,866 9 9
Distribution of gas—	
Salaries and wages of Officers (including Rental Clerks)	£2,195 17 0
Repairs, maintenance, and renewals of mains, service-pipes, and fittings, including labour	1,648 13 2
Repairs and renewals of meters and stoves	1,656 15 5
Public lamps—	
Lighting and repairing	5,501 5 7
Rent, rates, and taxes	2,102 2 6
Management—	
Directors' allowance	4,890 19 3
Company's Auditors	983 17 11
Salaries of Secretary, Accountant, and Clerks	75 0 0
Collectors' salaries and commission	1,039 9 6
Stationery and printing	1,576 2 3
General charges	391 6 4

OTTOMAN GAS COMPANY, LIMITED.

The Ordinary General Meeting of this Company was held last Tuesday, at the London Offices, No. 9, Queen Street Place, E.C.—Mr. E. HORNER in the chair.

The SECRETARY (Mr. A. J. King) read the notice convening the meeting; and the Directors' report, and the accounts for the half year ending June 30, reference to which was made in the JOURNAL last week, were taken as read.

The CHAIRMAN, in moving—"That the report of the Directors be received and adopted," referred briefly to the position of the concern. He thought the shareholders would find from the accounts that the Company had not gone back in any way; but, on the contrary, that they were quite as sound—perhaps rather more so—than they were at the close of the June half of 1887. The most important feature was that they had £1258 more cash in hand than they had at the end of the corresponding period. This he considered exceedingly satisfactory. The wages and materials had cost about the same. The item of lamp-lighting was £36 less. Salaries and office expenses had cost them £285 less. He called attention to these things to show that great pains were taken by their Engineer and Manager (Mr. H. W. Andrews) to do the best that was possible for the Company at Smyrna. On public lights they had received £147 more; but the payments by general consumers were unfortunately £54 less. The other items all stood very well indeed. The gas made per ton of coal amounted to 10,308 cubic feet; and the unaccounted-for gas was 8½ per cent. He thought they might congratulate themselves on the way in which the concern was going on, notwithstanding the very depressed state of affairs in the East, especially in Smyrna. Great credit was doubtless due to their officers for this condition of things.

Mr. A. J. DOVE seconded the motion, and it was carried.

The CHAIRMAN next moved the declaration of a dividend at the rate of 7 per cent. per annum on both classes of shares, free of income tax.

Mr. A. CLARKE seconded the motion, which was agreed to.

The CHAIRMAN, in proposing a vote of thanks to the officers of the Company, said that it was perfectly clear that great difficulties occurred in such a place as Smyrna. Mr. Andrews had recently had very arduous circumstances to contend with. Only lately he had been twice back from Smyrna on the Company's affairs. The Directors, seeing that he had done so much for the Company, had determined at their meeting that morning to present him with £100.

Mr. A. CLARKE seconded the proposition; and it was heartily acquiesced in by the shareholders.

Mr. ANDREWS, in reply, said it afforded him great pleasure to be at the meeting. He was returning to Smyrna the next day; and he should, especially after the substantial manner in which the shareholders had acknowledged his services, start back with renewed vigour and energy. Alluding to the position of the Company, he said he thought they would all like a little more dividend; but Smyrna had, as the Chairman had mentioned, been passing through a most depressed time. However, there was no doubt that the tide had now turned. It was true that the consumers' rental was somewhat reduced; but he confidently hoped they would overcome this little difficulty. It was a source of great happiness to him to receive the approval of the shareholders; and the Board had always treated him with the greatest kindness and cordiality. Of their Secretary (Mr. King) he could not say a word too much. The 15 years he (Mr. Andrews) had been connected with the Company seemed a long term; but Mr. King had been with the Company longer.

Mr. SHAND moved a vote of thanks to the Chairman and Directors, and expressed great satisfaction at the economies which had been introduced by Mr. Andrews.

Mr. R. L. ANDREWS seconded the motion, which was carried *nem. con.*

The CHAIRMAN acknowledged the vote, and the proceedings terminated.

HARROW DISTRICT GAS COMPANY.

The Half-Yearly General Meeting of this Company was held at Harrow on Monday last week—Mr. J. GLAISHER, F.R.S., in the chair.

The ENGINEER and SECRETARY (Mr. J. L. Chapman) read the notice convening the meeting, and the report and accounts, which were referred to in the JOURNAL for the 11th ult. were presented.

The CHAIRMAN, in moving the adoption of the report, said if the shareholders compared the balance-sheet with that for the corresponding half of 1887, they would see how similar they were, both as to the creditor and the debtor sides. It implied great uniformity of work—a uniformity more than he liked, for the progress was not such as one might expect in a suburban district like theirs. In other districts, gas companies had doubled their work in about ten years; but they had not done so, although they had been in existence fifteen years. What could be the reason? What blighting influence was at work in their beautiful district of Harrow: for beautiful it was. When there was the talk of the Metropolitan Railway coming to Harrow how often he spoke to the shareholders about the change that was to take place. The railway had come, but the hope that he had indulged in was a "hope deferred." Still he did not despair. It was impossible for so beautiful a district not to improve. In looking to see whether there was any progress, he considered first the consumption of coal, and took it for four half years. In 1885 it was 1265 tons; in 1886, 1308 tons; in 1887, 1388 tons; and now it was 1394 tons. This showed only 6 tons increase over the corresponding half of last year; but still it was an increase. At this rate, he would not see the figures doubled in his time. There was, however, an indication in the balance-sheet that they were in progress. Then as to the price of coals, he found that in 1885 they paid 18s. 2d. per ton; in 1886, 18s. 3d.; in 1887, 17s. 9d.; and now it was 17s. 8d. This was very important to them; and the Directors would keep their eyes open, and see if they could not purchase it at a still cheaper rate. They obtained more gas from their coals last year than they did previously, and the leakage was less; so that there were several indications that they were progressing. Their desire was to bring down the price of their gas to please everybody, or at any rate the majority; and this they would do as soon as it was in their power. They had to contend with the electric light, though he did not think it was very important. It was a luxury indulged in by those to whom money was no object. But it happened that money was an object to most people; and therefore most people could not have the electric light. Then there was petroleum. This was a nice light, but it gave a good deal of trouble. When people took up petroleum they were generally pleased with it at first; but the trouble it necessitated soon caused an alteration in their feelings. Gas, on the other hand, was extremely convenient, and caused no trouble whatever to the consumer. Then they had to contend with their residuals. Their coke in 1885 realized £312; in 1886, £355; in 1887, £373; and in 1888, £370. He was rather surprised at the falling off; but they were in a difficulty at the present moment because there was a great quantity being sent over to the north side from the south side of London; the figures in respect of tar were: 1885, £131; 1886, £104; 1887, £38; and 1888, £53. All their tar was now used on the works; and by doing this they saved coke, for which they

received more money. For their ammonia they realized twice as much as they did in 1885. Taking the totals of all the residuals, they had £485 in 1885, £520 in 1886, £490 in 1887, and £510 in 1888. Therefore, viewing the balance-sheet critically, as he had endeavoured to do, he was more hopeful after examination than he was before. He was at first rather depressed, but when he looked at the several items he was cheered again. He afterwards asked himself, "Had they earned the dividend?" Yes. "Did they do it last year?" No; they had to draw on their undivided balance. This confirmed the hopeful view he took after examining the accounts carefully. Some cheering news had been given him that morning, when he was told by one of his brother Directors that six or seven of his large houses had recently been let in Harrow. This was what he wanted to see. If every house was taken in the place, there would be a greater demand for gas, and the Company's prospects would be improved. Though not prospering at the rate of similar undertakings, the Company had in it success; and he hoped before long the hope that had been indulged in for so many years would be realized.

The DEPUTY-CHAIRMAN (Mr. John Chapman) seconded the motion, remarking that he quite agreed with what Mr. Glaisher had said especially with the hopeful part of his speech, when he referred to the houses that had recently been let in Harrow. Certainly things began to look a little brighter. He agreed with their worthy Chairman that such a beautiful place as Harrow ought not to have so many empty houses. Notwithstanding the threatening circumstances around them, he trusted that they would yet see Harrow prosperous and happy. He was sorry the report did not show a more flourishing state of affairs; but he hoped it was a stepping-stone to something brighter in the future.

Mr. BROADBERRY referred to the differential prices charged by the Company, which he thought were likely to cause unpleasantness. As soon as the accounts would allow it, he hoped the Company would fix one general price for their gas.

The CHAIRMAN said the subject had been before the Directors several times; and as soon as they could clearly see their way to do it, it would be done. At present, however, they must "cut their coat according to their cloth."

The motion was then carried.

Subsequently dividends were declared as follows:—7½ per cent. on the original capital, 7 per cent. on the first additional capital, and 5½ per cent. on the second additional capital, all less income-tax.

On the motion of Mr. C. HORSLEY, J.P., seconded by Mr. A. H. BAYNES, F.R.A.S., a vote of thanks was unanimously passed to the Engineer and Secretary and to the Auditors.

Mr. J. L. CHAPMAN, in responding, said that he was extremely glad that the shareholders were pleased with the balance-sheet. With petroleum sold in the streets, it was not so easy as in the days gone by to carry on their works; but he believed with the Chairman that oil had only a passing popularity. The Chinese Government, he noticed, were striving at the present time to prevent the importation of kerosene into the country, as having a more deleterious effect than the opium traffic. He did not think it would suit the public taste long in this country. They had held their own better, he thought, than they could have expected. He trusted that with the reduced price of gas they would get more consumers, and so be enabled to go ahead more rapidly than they had done in the past.

Mr. J. RANDALL, in responding for the Auditors, said it was always a pleasure to go over the accounts; the only thing he regretted was that the figures were not larger. He could tell the shareholders that the price of oil was likely to go up; and that would be better for them, for they would have less to compete against. Let them reduce the price of gas as much and as soon as they could. Their progress was slow, but it was sure.

Mr. BROADBERRY then moved a vote of thanks to the Chairman and Directors for their able conduct of the business of the Company.

Mr. NOWAKOWSKI seconded the motion, and it was carried unanimously. The CHAIRMAN briefly acknowledged the compliment, and the proceedings terminated.

SHREWSBURY GAS COMPANY.

The Annual General Meeting of this Company was held last Thursday—Mr. A. G. BROOKES in the chair.

The SECRETARY and MANAGER (Mr. W. Belton, Assoc. M. Inst. C.E.) having read the notice convening the meeting, the report of the Directors was taken as read. It stated that the available balance of profit amounted to £5564 17s. 9d., out of which the Directors recommended that the authorized dividend should be declared. There was a small increase in the consumption of gas during the year, and also a slight improvement in the returns for residuals. The unaccounted-for gas was 4·38 per cent. The reserve fund now amounts to £6876 4s. 7d. and is invested in 2½ per cent. Consols. The Directors have deemed it advisable to revise the prices charged for the rental of meters, and have reduced them to about half the amount hitherto charged; the reduction to take effect from June last.

The CHAIRMAN, in moving the adoption of the report, said it was satisfactory that the Company would not have to raise more capital for some time, because they had a considerable balance in hand and the expenditure was very low. The shareholders would observe that there had been an increase of rather more than 2 per cent. in the sale of gas during the year; the total quantity consumed being 115½ million cubic feet. The unaccounted-for gas had only been 4·38 per cent.; and it spoke well for the admirable way in which the works were conducted that the loss should be so small. He had been in the habit of reading the JOURNAL OF GAS LIGHTING, and found that there were very few gas companies in England who could boast of so small a loss. The sale of residuals had improved; but the price had been low for some years. Notwithstanding this, they had managed to survive difficulties. With regard to the reductions they had made in the rental of meters, alluded to in the report, they amounted to about one-half the amount the Company had formerly charged; and the Directors believed that this concession, which gave the consumers about £250, would be a source of general satisfaction. They had the more pleasure in making these reductions because it greatly relieved the smaller consumers, whom he thought the Company would be always willing to help. It was of much consequence to them, as the shareholders would agree with him when he mentioned the fact that occasionally in a quarterly payment the charge for a meter was sometimes greater than for the gas itself. He was sure, therefore, that this concession would meet with their approbation quite as much as any action of the Directors on their behalf. He thought he could fairly congratulate them upon the excellent condition of their property, and the prospects of continued success. They had an increasing reserve, which at present amounted to more than £6876, and the balance of profit was increasing. Taking these matters into consideration, he thought the shareholders would agree that the position of the Company was most satisfactory.

Mr. HUMPHREYS, in seconding the motion, said it gave great pleasure to the Directors—and he was sure also to the shareholders—that they were able to render so satisfactory an account of their stewardship. As the

Chairman had remarked, it was stated in the report that they intended to make considerable reductions in the rental of meters, which was highly satisfactory. Whilst protecting their own interests, they were enabled at the same time to further the interests of the public in general, not only by the reduction in the charges for meters, but also by other prospective reductions in the price of gas itself.

The motion was carried unanimously.

A dividend at the rate of 7½ per cent. per annum was then declared.

The retiring Directors and Auditor having been re-elected,

A cordial vote of thanks was accorded to the Chairman and Directors for the able manner they had conducted the affairs of the Company.

The CHAIRMAN, in acknowledging the compliment, said he was not surprised at the success of the Company when he took into consideration the admirable management they had. In his candid opinion, he believed that as a Manager in every capacity Mr. Belton could not be surpassed. To him, therefore, was the credit due.

Mr. BENTLEY then proposed a vote of thanks to Mr. Belton; referring in flattering terms to the manner his duties had been discharged.

Mr. BOWEN seconded the motion, and it was cordially agreed to.

Mr. BELTON having returned thanks, the services of the Auditors were suitably acknowledged, and the proceedings closed.

THE RISE AND PROGRESS OF THE SOUTHAMPTON GAS COMPANY.

In a recent edition of the *Southern Echo* there appeared an article containing an interesting account of the rise and progress of the Southampton Gas Company, from which we take the following particulars:—The works were originally in the hands of Messrs. Barlow Bros., who disposed of the property to the Company in 1823, when the district could not boast of more than 14,000 or 15,000 inhabitants. As may well be supposed, the extent of the works and the character of the manufacturing processes employed were very different from what they are at the present day. The area was restricted, and the plant crude; and consequently the operations were costly. It appears that the supply to the consumers was regulated by the class of burner selected and the number of hours the gas was used. For an Argand burner the annual cost of gas ranged from £3 to £8; for a similar burner of larger size, the annual cost ranged from £4 to £10 10s.; for a small burner, used in a passage or fanlight, the charge was £3, £3 10s., or £6, according to the number of hours; for a batwing or "tulip" burner, out of doors, the price was £5 if used from dusk till eleven o'clock, £5 16s. 8d. if used till twelve o'clock, and £10 if kept alight till sunrise. Where the gas was consumed either on Sunday or in the morning, one-sixth was added to the price. Persons whose consumption was irregular were recommended by Messrs. Barlow to be supplied by measure, at the rate of 15s. per 1000 cubic feet. The terms of payment were very exacting; all consumers being required to engage a burner for twelve months, and to make their payments in advance. The proprietors would not supply gas unless the burners were fixed by themselves and paid for, together with the fittings and pipes running into the house. On Saturday night the lights were allowed to burn till eleven o'clock without additional charge to the consumer. "The regulations of Messrs. Barlow might," says the writer of the article, "have been practicable in the days of our forefathers, but they wear a ludicrous aspect when compared with our modern notions of the law of supply and demand. Under such conditions, it was natural that gas should not occupy a very prominent place in the regard of the public." When the undertaking passed into the hands of the Southampton Gas Company, economies were periodically introduced, until the Directors were able, in 1886, to reduce the price of gas to the limit of 4s. 6d. per 1000 cubic feet, and now 3s. is charged in the town. The population stands at about 70,000; and the Company own mains which, in the aggregate, are nearly 100 miles in length. Gas is not only supplied to Southampton proper, but to the outlying districts. In these the Company now charge 3s. 6d. per 1000 cubic feet, or 2s. below the maximum price allowed by Parliament. They served 1314 public lamps, and have a total of nearly 5500 consumers on their books. The Company became incorporated in the year 1848; additional powers being obtained in 1865 and 1876. The total authorized capital, share and loan, is £286,660, of which £189,858 of the share capital has been paid up. The Company have also availed themselves of their borrowing powers to the extent of £96,660, and have realized £19,424 in the shape of premiums on the sale of shares by public auction. There has of late years been an enormous increase in the quantity of gas sold. In December, 1849, the works were capable of producing in 24 hours 116,000 cubic feet of gas. In the corresponding month of 1887, 1½ million cubic feet of gas were produced. This great increase will represent the gradual progress made by the Company, especially in regard to their works. It cannot be said, however, that the income of the Company has augmented to an extent corresponding with the opening out of new districts. The writer then proceeds to give a description of the Company's works.

THE LUTON CORPORATION AND THE GAS AND WATER WORKS.—A special meeting of the Luton Town Council was held last Friday to receive the report of the Committee appointed to consider the advisability of the Corporation purchasing the water and gas works. The Committee were not in a position to make any recommendation with regard to the gas undertaking; but, after considering the figures placed before them concerning the water-works, the Council resolved to take the necessary steps to purchase the concern.

A QUESTION OF PUBLIC LIGHTING IN NORTH WALES.—The ratepayers of Rhoslanerchrugog, near Ruabon, had an exciting debate last Wednesday evening on the subject of lighting the streets with gas. The matter occupied the attention of the Vestry in June last year; but no decision was come to—the question being ordered to stand over for a year. There was a pretty general agreement among the assembled ratepayers on Wednesday as to the necessity of having lights in the main thoroughfares; and the Gas Company had expressed their willingness to act liberally with the parties. It was estimated that 40 lamps, in addition to those in front of some of the shops, and a large one promised by the Company, would be sufficient; and for these the charge would be £80 per annum. This, according to the rateable value, would entail a rate of 2½d. in the pound, or, with the cost of collection, perhaps 3d. This, it was considered, the ratepayers would not be able to bear in addition to the present taxation. It was contended by some speakers that the 40 lamps proposed would be altogether inadequate; while others maintained that they would be in excess of the requirements of the place. After much confused discussion, a motion was submitted to defer the matter for another year. To this an amendment was moved to adjourn it for a fortnight. The proceedings at this point became uproarious—conflicting resolutions of various kinds being made with bewildering haste, and the opposition party showing signs of great excitement. Eventually the motion was carried by a majority of 40; and thus the town will be left in darkness for another twelvemonth.

BIRMINGHAM CORPORATION GAS SUPPLY.

WORKMEN'S HOLIDAYS.—INCREASE OF SALARIES OF OFFICIALS.

At the Meeting of the Birmingham Town Council to-day, the Gas Committee will present the following report:—The Gas Committee report that the memorialists for holidays to workmen have been informed that holidays will in future be granted as follows:—A holiday of one week (equal to 6½ days) in each year, during the summer months, to the firemen, stokers, machinemens, coke wheelers, coal trimmers, coal wheelers, and odd men—such men being described as carbonizers, or men working in the retort-houses—who have been employed not less than ten months in the year ending June 30; it being understood that such holiday is to be an actual holiday or rest from work, and that no money compensation is to be paid in lieu thereof. A holiday on Christmas day, Whit Monday, and the first Monday in August, or other days in lieu thereof, to all workmen who have been in the direct employment of the department for three months continuously prior to each holiday, other than the carbonizers, to whom the previous regulation applies; it being understood that such holiday is to be an actual holiday or rest from work, and that no money compensation is to be paid in lieu thereof. The annual cost of these holidays is estimated at £580. In compliance with a minute of the Council, the Committee report the salaries of officials of the department which have been increased during the present year. [Among these are, Mr. E. Smith, Secretary, from £1000 to £1250; Mr. W. H. Powell, Assistant-Secretary, from £250 to £300; and Mr. Charles Hunt, Engineer, from £950 to £1200; the remainder being small advances to various clerks.] The cost of repair of meters for the half year ended June 30 last was £2870 8s. 9d., and the number repaired was 4514. The quantity of coke in stock on Sept. 20 was 1072 tons, as against 469 tons at the corresponding period of last year. The quantity of gas sold in the quarter ended June 30 was 618,980,900 cubic feet, as against 594,663,600 cubic feet in the corresponding quarter of 1887; being an increase of 24,317,300 cubic feet, or a little over 4 per cent. The number of new services laid during the quarter ended June 30 was 371, as against 344 in the corresponding quarter of 1887, being an increase of 27.

LEICESTER CORPORATION GAS SUPPLY.

HALF-YEARLY REPORT OF THE GAS COMMITTEE.—REDUCTION OF METER-RENTS.—INCREASE OF THE ENGINEER'S SALARY.

At the Meeting of the Leicester Town Council last Tuesday—the Mayor (Mr. T. Wright) in the chair—the half-yearly report of the Gas Committee was presented. The Committee reported that the net profit of the undertaking, after payment of interest on the capital, for the six months ending June 30 last, was £14,881 17s. 8d., of which £2520 had been paid as the amount of the sinking fund for the same period. The net amount realized by the manufacture of residual products was £6841 10s. 2d., and by the gas-fitting business £447 4s. 2d. During the half year, 43,099 tons of coal were carbonized; the quantity of gas made being 437,494,000 cubic feet, as against 425,050,000 cubic feet for the corresponding half of last year, or an increase of 2·92 per cent. The average illuminating power of the gas had been a little more than 3 sperm candles in excess of the parliamentary standard. The new chemical works in the Aylestone Road were working in a most satisfactory manner, having been in full operation for upwards of twelve months. The extension of the Aylestone Road works was progressing satisfactorily; and there was every probability of the new works being completed within three years from the commencement, as anticipated. The Committee have had under consideration the question of making some reduction in the scale of charges for the use of meters. Those chiefly used by consumers were 3-light; and the Committee recommended that the rents of these should be reduced from 1s. to 8d. per quarter, which would represent a reduction of about £1000 a year in the income of the department. They had received an application from Mr. A. Colson, Assoc. M. Inst. C.E., the Engineer and Manager, for an increase of salary; and, having regard to the satisfactory manner in which he had, during a service of nearly six years, discharged his duties, and considering the increased work and responsibilities, they recommended that his salary be increased by £150 per annum.

Alderman Wood, in moving the adoption of the financial portion of the report, said it was a matter of increasing gratification to the Council that the profits of the Gas Department showed such continued progress. The profit of the half year just closed was the largest ever realized, except in two cases, since the works had been under the control of the Corporation. If they considered the fact that the price of chemicals now was only something like half of what it was in 1881, when in no single year up to that were they able to announce for a whole year a profit equal to that of the past half year, it would be seen that the present result was exceptionally gratifying. The half-year's working showed a net profit of £12,361 17s. 8d., against £9759 10s. 10d. for the half year ending June 30, 1887, or an increase of £2602 6s. 10d. This had not been obtained by any great saving in the price of coal. The average price had been the same as in the corresponding period of last year; but they had spent £500 more on coal, and had produced from it £1900 more revenue. This was very satisfactory; and he thought it right to say it was due, in a measure, to the full working of the regenerative furnaces which had come into operation entirely during the half year, and which had enabled the Engineer to produce so much more gas from a given quantity of coal. They had spent during the half year £120 more in purification. One significant fact was that, although they had had this increased revenue and larger demand upon the department, the wages had been less by £95. The works had been fully maintained. They had spent £4394 in repairs and maintenance, against £3370 in the preceding half year; so that the Council could judge that the works were kept in a thoroughly efficient condition. One unfortunate item of expenditure was the increased charge for rates and taxes. The Council were aware that a few months ago the assessment was raised in St. Mary's parish; and this would become a burden on the department to the extent of £1200 a year. The total revenue during the half year was £64,201, against £58,901; showing an increase of £5300. After deducting the extra charges, they had a net increase of profit of £2602. The sources from which the profit was derived were as follows:—The consumption of gas had increased nearly 3 per cent.; and they had realized £1963 more for gas than last year. From the rental of meters and stoves they gained £49 more; and from the sale of coke and breeze, £514 more. But the chief item of increase had come from the chemical works; the advance there being £2578. He wished to impress upon the Council the fact that this was not due to any material rise in the value of the products, but simply to the better plant they had to manufacture with, and the careful supervision of Mr. Colson, the Engineer, who had had this department entirely under his control. The gas-fittings department had brought an increased profit of £134. They had spent on the extension works during the half year £12,555; upon new mains (which meant extensions of mains) £1480; and on new meters, £417—making a total expenditure on capital account of £14,461. Consequently their interest charges were growing every half year. But in spite of this the general result of the department was very gratifying. One item which would materially affect the balance submitted to the Council was the stock. He thought it was well that he

should assure the Council that the stock-taking was done in the most careful and generous manner; and he believed there was a very large reserve fund in that stock. They had now completed 10 years of the working of the Gas Department; and he said it was a tribute to those gentlemen who took a leading part in prevailing on the Council and the town to purchase the gas-works (Alderman Windley and Winterton, and the late Alderman Grimsley). During this period the Corporation had realized a net profit of £210,000, £5000 of which had been placed to a reserve fund, £15,000 to the gas renewal fund, £28,560 to a sinking fund, and £146,700 had been handed to the Borough Treasurer in reduction of the rates.

Mr. LENNARD seconded the motion. He said he was not sure it was the best thing for the town and Council that these enormous profits should be made, because perhaps they were not so carefully spent by other departments as they would be if the money came directly from the rates. But whilst the present policy was sanctioned by the Council, it was the duty of the management to make the best they could of it. He should like to see some reduction made very soon in the price of gas, which would to a certain extent curtail the profits. But during the next two or three years they would have to spend £80,000 or £90,000 of capital, which would cost upwards of £3000 a year for interest, and would not bring in a penny of revenue. After this expenditure had been incurred—say, in five years—they would begin to reap a very much larger profit than they were doing now, because they would be working on enlarged premises, which would cost them about a third of the capital of the present premises, and then he thought the question of price should again claim attention. He confirmed the Chairman's statement as to the liberal method of taking the stock, and said that the happy result of the half-year's working was arrived at through the new works, the skill and close attention of the Engineer, and to the loyalty and hearty co-operation of the whole staff.

Alderman BENNETT said the return for every ton of coal carbonized was greater in Leicester than anywhere else in the country; and the difference produced by working up the residuals and selling them had, owing to the skill in which it was done, resulted in a profit of £7000 during the year.

Mr. G. GREEN expressed his appreciation of the work of the Gas Committee and the management, but reminded the Council that when they took over the gas-works it was thought they would ease themselves of a great deal of what was then paid as dividend to the shareholders. But now they not only paid the premium they had, but also that upon the purchase of the lease and the interest on the capital, besides providing a sinking fund which would repay the capital in 50 years; and beyond this they earned a profit of something like 20 per cent. He protested that the profits were much too large; and if in five years' time they were going to increase the profits, it was indirect taxation. It fell heavily on the great bulk of the consumers. On every £1 they paid for gas, there was 4s. profit; and he submitted that some relief should be given in less than five years. The trifling relief of £1000 proposed to be allowed on meter-rents was not worth considering.

The MAYOR called attention to the fact that the greater part of the last speech had been devoted to a question which was not now before the Council. Unless there was some definite motion to alter the system of dividing the profits, the discussion of the subject was irregular.

Alderman KEMPSON pointed out that a great portion of the profits was devoted to reducing the rates, and therefore the ratepayers derived the benefit.

Alderman WINDLEY thought they should not find fault with the one department of the Corporation which was doing good to the town. The gas-works more than realized the expectation of those who took them over; and the desire of the Committee had always been to obtain the best plant and the most economical and skilful management. If the result of this was to produce large profits, it was a matter for congratulation. At the same time the subject of profits had engaged the attention of the Committee at their last meeting. The question of lighting all the courts of the town would not be overlooked; and it was also suggested that a considerably improved method of lighting many of the streets might be adopted, at a lower rate to the Corporation than the ordinary charge.

Alderman WOOD said the fact had been lost sight of that reductions had been made from time to time in the price of gas, on the recommendation of the Committee. Whilst £146,000 had been applied to the lowering of the borough rate, about an equal sum had been applied in the reduction of the price of gas. It was, however, a fair matter of consideration to see in what direction—and possibly in favour of the consumer—they could make some alteration; and this matter would not escape the attention of the Committee. He hoped also that the Committee would see their way to improving the lighting of the town by reducing the charge for the public lamps.

The motion was then adopted.

Alderman WOOD then moved that the rent of 3-light gas-meters be reduced from 1s. to 8d. per quarter; remarking that this would entail an annual cost to the Gas Department of about £1000. At various ward meetings in the town it had been repeatedly suggested that the meter question should receive attention; and, after considering it for five or six months, the Committee had arrived at a unanimous recommendation. They had 14,735 of these meters on hire, which cost the department about 6d. each per annum for repair, and about 2d. each for removal and re-removal. This was a cost of about 8d. per meter to the ratepayers; leaving a net revenue of about 3s. 4d. each per annum. By the proposed reduction the net rent for this class of meters would be 2s., which would compare favourably with the rents paid for the larger descriptions of meters. A great deal might be said in favour of retaining the rent at the old price; but the Council should consider that the consumers using 3-light meters were working men, who deserved whatever remission could possibly be made.

Mr. LENNARD seconded the motion.

Alderman BENNETT opposed the recommendation, observing that if the object were to secure the popularity of the masses at the expense of the remainder of the ratepayers generally, no simpler plan could have been adopted; but this was the last consideration which would actuate Alderman Wood and those co-operating with him. He feared, however, that they did not appreciate the actual facts of the case. Out of the 14,735 3-light meters, a large number were rented outside the borough; and the cost of fixing varied from 1s. 6d. to 5s., according to distance. Many of these consumers lived in small houses, at weekly rents. It was the duty of the Council to consider the interests of the ratepayers as a whole; but the suggestion now made seemed lacking in fairness. They proposed to reduce the rent of the 3-light meters to a little over 9 per cent. Whilst, during the past few years, they had reduced the price of gas 8d. per 1000 cubic feet, he thought it exceedingly unfair to limit the benefit now proposed to one section of the community, who would not appreciate it.

Mr. LENNARD denied that the Committee desired to obtain popularity in the manner suggested. They had been brought face to face with a gross anomaly as regards the charges for meters. Of the 19,000 odd meters out on hire, 14,735 were 3-light meters, which had paid them 19 per cent., as against 10 per cent. received from the 5-light meters; and what was

now proposed was to place both classes on the same basis. There were two or three alternative policies, one of which was not to charge anything for the meters, as was done at Birmingham and in Glasgow. But in this case the extra cost must be placed on the price of gas; and if they were to sink this revenue of £4300, and throw it on to the gas, the cost would thereby be increased 1d. per 1000 cubic feet. He regarded the course proposed as a wise one; seeing that meters were simply trade utensils used in the business of the department. So far from the smaller consumers being benefited at the expense of the larger ones, he contended that the smaller ones paid a portion of the expense which should fall on the latter. As, however, the Committee were not prepared to abolish the charges altogether, the next best thing was to charge a reasonable rate; and he, for one, regarded 10 per cent. as a good return. He pointed out that while the renters of the 3-light meters paid rates indirectly through their rents, they did not directly receive the benefits of the gas profits, seeing that at least 10,000 of the 14,000 houses of this class were compounded for. Consequently, as the landlords received the benefits and the tenants gained nothing, the reduction now proposed would go to those who most needed it. As to the statement that residents outside the borough would be put to greater expense and have to pay a large sum for fixing, it should be remembered that they also paid an additional 4d. per 1000 cubic feet for their gas. For all these reasons, he failed to see why the Council should any longer make an unfair use of the monopoly vested in them.

An amendment to the effect that the meter-rents should be reduced to 6d. each was proposed and seconded; but, on Alderman Wood stating that the question would probably be considered in Committee on a larger basis, it was withdrawn, and the motion carried unanimously.

Alderman WOOD next moved that the salary of Mr. A. Colson, the Engineer and Manager of the gas-works, be increased by £150 per annum. He said that in making this recommendation the Committee felt they were only proposing a simple act of justice to one who had devoted the whole of his ability and energy to the welfare of the Gas Department. Mr. Colson entered the service of the Corporation about six years since; and 2½ years ago he received an advance of £150 per annum in his salary. When he was appointed Gas Engineer in succession to Mr. Robinson, he simply took over the control of the gas manufacture. Before he had been with them very long, it was found necessary to make an extension of the retort-house and erect new chemical works, the responsibility of which he accepted; and he had carried out the work most satisfactorily, without a single accident, or an error in the estimates. Since that time they had embarked on further extensions, which would ultimately cost £150,000, and which had so far been solely superintended by Mr. Colson in a most satisfactory manner. It should also be mentioned that some 18 months ago Mr. Colson voluntarily took over the management of the Chemical Department in succession to Mr. Tunbridge, who resigned. This department also had been most satisfactorily managed; the results being greater than were ever before realized. In view of these responsibilities, the Committee felt that the application made for an increase of salary was a just one; and it received their unanimous recommendation. Having spoken further in testimony of the devotion to duty displayed by Mr. Colson, the speaker expressed a hope that the increase would be sanctioned with equal unanimity.

Mr. LENNARD, in seconding the motion, pointed out that the members of the Council were recently, on the occasion of their visit, afforded an opportunity of judging for themselves as to the success of the works and the ability of the Manager. It should also be remembered that in connection with the new works, which involved an expenditure of £150,000 or £160,000, he had saved £6000 or £7000 as architect and engineer. Under these circumstances, he trusted the recommendation would be adopted.

The motion was carried unanimously.

COVENTRY CORPORATION GAS SUPPLY.

REDUCTION IN THE PRICE OF GAS.

At the Meeting of the Coventry City Council last Tuesday—the DEPUTY-MAYOR (Alderman Maycock) presiding—a report was presented by the Gas Committee, recommending that, as from the 30th ult., the price of gas should be reduced within the municipal boundary from 3s. to 2s. 9d. per 1000 cubic feet, and outside the boundary from 3s., 3s. 6d., 4s., and 4s. 6d., to 3s., 3s. 3d., and 3s. 9d., according to the distance from the city. To large consumers consuming from 200,000 to 300,000 cubic feet per quarter, an abatement of 1d. per 1000 cubic feet to be allowed; to consumers of 300,000 to 400,000 feet, an abatement of 2d. per 1000; and to consumers of above 400,000 feet, 3d. per 1000.

Mr. ANDREWS, the Chairman of the Committee, in moving the adoption of the report, said he thought every member of the Council was aware that their investment in the purchase of the gas undertaking had turned out to be a great financial success; so much so, indeed, that the last report showed that, after meeting all the instalments of the sinking fund, there remained a surplus profit of no less than £5600 on fifteen months' trading. It was estimated that during the current year, if the amount of gas consumed in Coventry was the same as during the preceding twelve months, the surplus profit would be about £3000 after paying all expenses. The question arose as to the method they should adopt in dealing with the surplus. They could not do as they pleased with it, because they were bound by the Coventry Corporation Gas Act, which prescribed exactly what they were to do with it. They had the choice of three alternatives. They might reduce the price of gas; or increase the annual payments on account of the sinking fund, so as to complete the purchase of the works in a shorter period than the 60 years prescribed by the Act; or they might apply the profits in the relief of the general district rate. But there was this difference between the methods—that if they allowed the matter to go on until the end of the year, to be dealt with at that time, the Act compelled them to let the whole of the profits go to the district rate fund. So that if the Committee wished to reduce the price of gas, the matter must not be allowed to drift, but must be dealt with in advance. This was the reason of the present report. The Committee were of opinion that the gas consumers, who had provided them with so handsome a surplus, had the first claim upon their consideration. The new tariff was based upon the broad principle that those citizens who had taken upon themselves the responsibility of the purchase of the gas-works, and who had risked their finances and property in so doing, were entitled to have the gas at a cheaper rate than outsiders, who had taken no immediate, and would bear no share of future, responsibility. It was therefore proposed to make the price of gas rather lower in the city than outside. In other words, under the new tariff, no premises would be entitled to be supplied with gas at the lower rate, unless they were also charged with the district rate. The existing gas tariff was the result of growth during a long period, and was full of anomalies. The proposed tariff was a much simpler one; and, as far as possible, an attempt was made to remedy existing anomalies. It provided that the price of gas within the municipal boundary should for the future be 2s. 9d., and outside 3s. 3d. per 1000 cubic feet—a difference of 6d. There were, however, two exceptions to this rule, one being that three small outlying districts which used a small quantity of gas, and which required a long length of main to supply them, would under the new tariff pay an

additional 6d.; making 3s. 9d. per 1000 cubic feet. At present two of these districts paid 4s. 6d., and the other 4s.; so that there would be a reduction of 3d. in one case and 9d. in the other two. In the other there would be no reduction there; the inhabitants of the places concerned would pay the same price as at present—3s.—because the Committee believed it would be impolitic to advance the price anywhere. As to the concession to be allowed to large consumers, at present when a consumer burned more than 500,000 cubic feet in a quarter, a concession of 2d. per 1000 cubic feet was made. A very large quantity of gas was at present consumed in manufactories—to a much greater extent than most people were aware of. The Committee believed that, in a large manufacturing city like Coventry, cheap gas was a necessity to their manufacturers, in order to enable them to maintain their position against competition elsewhere—that, in fact, cheap gas was one of the necessities of modern civilization. Therefore an increased concession was proposed to be made to large manufacturers. Instead of granting them the old reduction of 2d. per 1000 cubic feet when in any single quarter they happened to consume more than 500,000 cubic feet, it was proposed when they consumed 200,000 cubic feet to make them an allowance of 1d. if they did not exceed 300,000 cubic feet; on between 300,000 and 400,000 cubic feet, 2d.; and on 400,000 cubic feet and upwards, 3d. Another object in these concessions was to hold their ground against the competition which had lately been introduced in the form of Dowson gas—a cheaper kind of gas which could be used by the Coventry manufacturers in the same way as coal gas. One firm had already introduced the new gas—manufacturing it themselves—with the result that there was an enormous decrease in the quantity they consumed from the gas-works. It was believed that by granting further concessions to the manufacturers who used large quantities of gas, they would succeed in throwing the balance in favour of coal gas against the Dowson gas. The Committee believed this recommendation to be a sound one, in view of the well-known fact that it was a universal experience that the cheaper gas was supplied the larger would be the consumption; and they had ever believed it would tend to increase the consumption in Coventry. Such being the case, it would react in this way—that as gas could be manufactured much more cheaply on a large than on a small scale, with increased consumption there would be a further tendency for the price to be lowered. Referring to the amount required to meet the proposed concessions, he said the reduction in price would absorb £2091; and the concessions to be made on large quantities, £378—making a total of £2469. This would leave at the end of the year between £500 and £600 to be dealt with as the Council might think fit. The question might arise with some members of the Council, as to whether this operation was not a rather hazardous or risky one. He would at once reply that there was no risk at all about it. So far as he could see, there were only two points upon which any risk was likely to be run. The first was that they might imagine that during the coming winter, through bad trade or some other cause, there might be a decreased consumption of gas in the city, which would probably throw out their finances a little. In reply to this he might remark that the consumption for the six months of the current year already passed showed an increase of 7 per cent. in the quantity consumed; so that at present there was no probability of a decreased consumption. But even if there were, the 7 per cent. would probably more than compensate for it. So that in any case they might take it for granted that the total consumption in the current year would not be less than for last year. The other point upon which they might imagine there would be risk, was the chance of a slight advance in the price of coal. But even if there was, there would be a corresponding increase in the selling price of the residuals. They would obtain more for their coke; so that there was very little fear on this point. But, further, in case of any mishap with their finances, they had their reserve fund to fall back upon, which had been built up to the full amount of £5000. Then there was the fact that they were getting 6s. more per ton for tar, and 1s. 3d. more for coke. Then they had also the fact that gas could be made cheaper in large than in small quantities; and that during the first six months of the present year the tariff had been the old instead of the new one. The Council would therefore see that there was nothing to fear in the proposed reduction, and that the move which the Gas Committee had made was a favourable one.

Mr. SUTTON seconded the motion.

Alderman DALTON said before the resolution was put to the Council he should like to congratulate Mr. Andrews on having drawn such a rosy picture, and, in the main, one with which he entirely agreed. Mr. Andrews had alluded to two or three reasons why they should not consider the step a risky one; but he had left out entirely—because, perhaps, it had not occurred to him—a very important reason why the proposals might be considered risky. This he should be happy to point out to Mr. Andrews privately, for he was quite sure there were risks in store that had not been alluded to.

The report was adopted.

ALFRETON WATER SUPPLY.—When it became necessary some years ago for the Sanitary Authority of Alfreton to construct water-works to supply the parish, it was decided to construct a reservoir and use the water from the Butterley pump, near Ashover. The original estimate was £20,000; but an expenditure of £40,000 has not yet resulted in obtaining a supply worthy of the name. The Lyndnay reservoir—the most costly part of the works—has proved comparatively worthless, having failed to hold any large quantity of water. The matter is at present under the consideration of the Alfreton Local Board.

THE ROCUDALE GAS COAL CONTRACTS.—A special meeting of the Rochdale Gas Committee was held last Wednesday, to consider the charge made by Mr. E. Evans at the town's meeting, as reported in last week's JOURNAL (p. 558). Mr. Evans's statement was to the effect that an exactly similar class of coal to that accepted by the Committee was offered at 1s. per ton less than the price paid to the Wigan Coal and Iron Company, who obtained the contract. The member of the Committee on whose authority Mr. Evans made his statement attended the meeting, and volunteered to send an explanatory letter to the papers; and this the Committee thought would be satisfactory. In his letter, the gentleman in question—a Mr. Parker—says: "In my statement I intended to convey to him (Mr. Evans) that in dealing with the tenders the Committee did not give them the attention which the importance of the subject demanded. My objection was to the position taken by a member of the Committee proposing that a deputation be appointed to wait upon the Wigan Coal and Iron Company 'to make the best terms they could' before any of the other tenders were considered. I protested against this proceeding, with the result that some slight consideration was given to a few of the other tenders, with the further result that the original motion was carried, and the contract entered into. My protest was made from a knowledge of the fact that some of the collieries offered a coal at 1s. per ton less which was of a similar quality, and in my opinion equal in every respect for gas-making purposes." It is anticipated that reference will be made to the subject at the Council meeting to-morrow, and an explanation given by the Chairman of the Committee (Alderman Petrie).

EDINBURGH AND LEITH GAS COMMISSION.

At the Meeting of the Edinburgh and Leith Gas Commission on Monday last week—Lord Provost CLARK presiding—various matters which came under consideration call for brief notice.

The Finance Committee reported that the assessable rental of the pipes of the Commission in Edinburgh had been fixed by the Assessor at £26,617; being an increase of £5966 on last year's rental. In Leith the rental was put at £4703; being the same as last year. In the county of Mid-Lothian it was put at £626; being an increase of £140. The total assessable valuation was thus £31,946, or an increase on last year of £6106. The Committee recommended the Commission to acquiesce in the valuation. The report was approved.

The minutes presented by the Finance Committee stated that the Clerk had been instructed to obtain delivery of Mr. G. Livesey's awards, and remit to his agents his fee of 250 guineas for acting as Arbitrer, and their own account of £24 10s. The Clerk read a summary of the awards as to the sums to be paid by the Commissioners for the coal, materials, &c., at present in possession of the two Gas Companies. The total to be paid to the Edinburgh Company was £15,808 0s. 8d., made up as follows:—For coal, £9202 1s. 10d.; materials, £3256 3s.; meters, £3159 8s. 4d.; and gas within holders, £190 7s. 6d. The amount to be paid to the Leith Company was £5875 15s. 11d. for stores, &c.; and for gas supplied to consumers between the 11th of May and the 31st of July, £5973 3s. 9d. These sums made together £27,657 0s. 4d. Authority was given to borrow the necessary amount on capital expenditure to pay the amounts named.

The Clerk also read a letter from Messrs. Davidson and Syme, W.S., requesting payment on behalf of the Edinburgh Company, of the above sum of £15,808 0s. 8d. It was pointed out that this amount was by the recent Act payable as at the date of transfer, and, therefore carried interest at 5 per cent. from the 1st of August until paid. The agents also desired payment, in the name of gas supplied to consumers and meter-rents from the spring quarter to the 31st of July, less 10 per cent., of £10,593 10s. 1d. This sum was payable, it was stated, subject to deduction of discount on the bank charge for advancing the money between the date of payment and the 11th of November. The Directors were desirous of having all matters immediately settled, as they considered it was their duty to the shareholders now to divide the funds, and, for various reasons, it was not desirable that they should be making interim divisions. Some conversation took place as to the liability of the Commissioners to pay the interest claimed; and eventually the whole matter was remitted to the Finance Committee, with powers.

The Clerk read a petition by *employés* at the Leith works, setting forth that in May, 1886, they had been apprised of a concurrent reduction of wages in all the principal gas-works throughout the kingdom, and they had agreed to a reduction, under the impression that it was necessary in the circumstances. The Edinburgh Company's workmen had, however, continued at the same rate of wages as at the date mentioned; and the petitioners therefore asked a readjustment of matters in keeping with their former position—"knowing," the petition stated, "that beneficence is accompanied with such an inward satisfaction that the duty is sufficiently rewarded by the performance." Bailie Garland (Leith) said the feeling seemed to be that the request was a reasonable one, and that the workmen in both places should be put on an equal footing; but ultimately the matter was sent to the Works Committee for consideration and report.

The Clerk submitted a certified statement of the expenses incurred by the burgh of Leith in connection with the parliamentary proceedings on the gas question, amounting to £1009 10s. 11d. The accounts were certified by the Provost and Town Clerk of Leith; and they were remitted to the Finance Committee, with power to authorize payment.

Mr. R. Mitchell, the Superintendent of the Edinburgh works, brought before the Commissioners a plan of proposed alterations in the carbonizing works in New Street. At present the carbonizing power is 239 tons per 24 hours; and it was proposed to increase the number of retorts, so as to have a carbonizing power of 480 tons per day. The result of the alterations would, it was stated, be a saving of £4000 per annum, arising from economy in labour. The matter was remitted to the Works Committee for consideration and report.

A few other matters of minor importance were then disposed of, and the business ended.

THE EXTENSION OF THE WILTON CORPORATION GAS-WORKS.

LOCAL GOVERNMENT BOARD INQUIRY.

Last Wednesday, Mr. S. H. TERRY, Assoc. M. Inst. C.E., attended at the Municipal Offices, Wilton, to hold an inquiry, on behalf of the Local Government Board, respecting an application made to them by the Wilton Corporation for sanction to borrow £7000 for the purposes of their gas undertaking. It may be remembered that the condition of the gas-works was reported upon about four months ago by Mr. Norton H. Humphrys, Assoc. M. Inst. C.E., of Salisbury, who had been called in by the Corporation for the purpose; and he was present at the inquiry, together with the Town Clerk (Mr. H. J. King), several members of the Town Council, and others interested in the matter.

The TOWN CLERK having read the notice of the application, and explained the action taken by the Council up to the date of the inquiry, proceeded to state that the Corporation had already obtained parliamentary powers to purchase the gas-works, and simply wanted money to complete it, and to improve the works. The total of £7000 was made up of various items; that for the estimated cost of the probable expenditure on additional new mains and for mortgages being for actual work. They did not anticipate that they would require all the money asked for; but they might do so. There were no estimates prepared of the proposed works.

The INSPECTOR remarked that he did not think the Local Government Board would allow the Corporation to borrow money on probable expenditure, even if he sanctioned it.

The TOWN CLERK said he purposed calling the Engineer to describe the present condition of the works, and what the Corporation proposed to do. The assessable value of the borough in 1877 was £3144 19s. 6d.; and there would be no debt in 1892, except the gas-works loan. The rates averaged 3s. 3d. in the pound; but in 1892 they would be largely reduced.

Mr. Humphrys then explained at great length the work intended to be carried out. He said the present maximum demand for gas was 25,000 cubic feet per day; but it was not possible to make more than 20,000 feet. They had no exhauster, and this made a great difference in the cost of production; but they proposed to have one—having described the state of the retort-house and the retorts, he said that the present arrangements in regard to the residual products were very unsatisfactory. After going into further technical matters he condemned various parts of the works.

The INSPECTOR: Then what you have bought is practically the goodwill of the business and the mains in the streets only.

Witness: Well, we are using in the things as well as we can. One of the holders is very good; it is 31 ft. 6 in. in diameter and 16 feet high, and will contain about 10,000 cubic feet. The maximum demand is 25,000 cubic feet per diem.

The INSPECTOR: Then at present you have not a proper quantity

of storage space. There must be some very extensive leakages in the town, I should think.

The TOWN CLERK: There have been no end of leakages reported at the works.

The INSPECTOR referred to the other holder, which was condemned, and asked what was the size of it.

Witness: Its diameter is about 30 feet; and it will hold about 6000 cubic feet of gas. It is thoroughly rusted, and was leaking considerably when I examined it.

The INSPECTOR: You want more storage capacity. I understand the present works will make 25,000 cubic feet of gas per day.

Witness said he did not so state. The 25,000 feet was the maximum demand; but in the condition in which he found the works, they could not make more than 20,000 cubic feet per day. He then proceeded further to explain the proposed alterations; saying that there would be three benches of five, two, and three retorts, which was the best arrangement under the circumstances, as they would be able to give a small, a medium, or a large supply, as might be needed.

The INSPECTOR, having examined the plans, inquired if anyone desired to address him in opposition to the application.

Various questions were then put; and from the replies and the conversation which followed, it was ascertained that a very small proportion of the inhabitants were consumers, and that the price of gas was rather high.

The INSPECTOR pointed out that the Corporation would probably be able to reduce the price considerably; and, having the works in their hands, be in a position to make more gas for the same money, or the same quantity of gas for less money. They would also be able to induce people to use more gas for cooking purposes in the summer. There would be no charge upon the ratepayers for the gas-works. They would be self-supporting; and any profit which might accrue would be applied to the reduction of the price of gas, maintenance of the plant, &c., and the balance would be devoted to the district rating fund. Under their Provisional Order, the Corporation could reduce the price of the gas, but were not obliged to go lower than 4s. per 1000 cubic feet.

The TOWN CLERK, in answer to questions, stated that the Corporation hoped to reduce the rates by the profits on the gas supply; and that they expected to be able to do the public lighting for nothing.

After some further conversation, in the course of which the Inspector expressed the opinion that the money spent in increasing the holder capacity was well laid out, the inquiry closed.

The Inspector, the Town Clerk, Mr. Humphrys, and others, then went to the gas-works and examined the extensions as in progress; Mr. Terry being favourably impressed with what he saw. It is understood that he will make the usual report, and will recommend that the sum granted be £6200; holding that the Local Government Board will not be able to sanction the item for probable expenditure.

THE SALFORD GAS COMMITTEE AND THE STOKERS.

The Gas Committee of the Salford Corporation held a special meeting on Monday last week to consider the disaffection which exists among the stokers employed at the gas-works, to which allusion has been already made. The Mayor (Mr. Alderman Dickens) presided, and there was a large attendance. The new arrangement to which the men object requires that each stoker shall carbonize 72 cwt. of coal per day; but he is not called upon to wheel his coal from the yard to the retort-house. The Committee were informed that in Manchester the stokers had only to carbonize 40½ cwt. per man per day; and they have not to wheel their own coke, as the Salford men are required to do under the new regulation. A deputation from the stokers, in the course of their interview with the Committee, affirmed that the work sought to be imposed upon them was too laborious, and that the new system would not confer any advantage on the Corporation. What they wished was to revert to the old plan which had worked well for two years—viz., that each man should carbonize 45 cwt. of coal per day, and wheel his own coal and coke. After the deputation had withdrawn, the Committee had a long discussion, and eventually a resolution was passed supporting the action of Mr. Shoubridge, the Gas Engineer and Manager, and deciding that the new system should be maintained—at any rate until its suitability or non-suitability had been properly tested.

Later in the day the following statement was issued by the Gas Committee:—"The General Gas Committee of the Salford Corporation, having held a meeting this morning, at the Town Hall, the Mayor (Mr. Alderman Dickens) in the chair, when a deputation from the retort-house workmen employed at the Regent Road Gas-Works attended to represent to the Committee that the modified system which was arranged between the Committee and the men on Monday last (Sept. 17), and accepted by them as in every way satisfactory, was found on trial to be impracticable. The Committee further ascertained from the deputation the grounds upon which the men declined to continue working on such modified system as arranged; and in reply to questions put by the Mayor, elicited the fact that the men were determined to resist the introduction of any change whatever, and that they would either revert to the old plan of working or send in their notices. The Committee, therefore, are desirous that the facts of the case should now be placed before the public. Under the old system each stoker loaded up and wheeled from the coal-shed to the retort-house 2 tons 5 cwt. of coal or cannel, which he then lifted into the retorts; he had also to withdraw and quench the coke, wheeling 19 cwt. of it into the yard, and to attend to two of the furnaces that heat the retorts, and remove 2 cwt. of refuse therefrom—handling in all 5 tons 11 cwt.—for which he received weekly wages at the rate of 5s. per shift (a day's work). Under the modified system, the coal is brought from the coal-store by a separate class of men called coal wheelers, who place it in the retort-houses ready for the stokers. The stoker's work consists in charging 12 retorts with a total of 3 tons 12 cwt. of coal, and withdrawing, quenching, and wheeling out the coke, amounting to about 1 ton 6 cwt.; thus handling a total of 4 tons 18 cwt., for which he is paid at the same rate as on the old system—viz., 5s. per day. This work affords the men every alternate hour for rest. The furnaces which heat the retorts are attended to by a separate set of men. It is obvious, therefore, that under the new or modified system the manual labour of the stokers is considerably less than formerly. After the most careful consideration of all the circumstances of the case, the Committee are satisfied that the complaints of physical hardship which the modified plan is said to impose have no real foundation; and upon inquiries being made from other towns, they have ascertained that the system proposed has been in operation (in one place for upwards of 15 years) without the slightest complaint. The Committee, having had from the commencement several communications with the men, and having endeavoured, by conceding the modifications referred to, to arrive at an amicable settlement of the dispute, they confidently appeal to the burgesses and gas consumers to support them during the present difficulty."

The Directors of the Wakefield Gas Company have decided in future to fix gas-meters free of charge to consumers.

BIRMINGHAM CORPORATION WATER SUPPLY.

THE PROPOSED ADDITIONAL WORKS.

At the Meeting of the Birmingham Town Council to-day, the Water Committee will present a report, in the course of which they make the following reference to the proposal (already alluded to in the JOURNAL) to raise further money for carrying out permanent works in connection with the water undertaking:—"Application was made to the Local Government Board for their sanction to borrow the final £100,000 authorized by the Act of 1875. In consequence of this application, Mr. John Thornhill Harrison, M. Inst. C.E., an Inspector of the Board, held an inquiry at the Council House, on Thursday, the 31st of May last. The reply of the Local Government Board was contained in a letter addressed to the Town Clerk, and dated July 10, 1888. The letter, so far as it related to the application of the Water Department, was as follows:—"The Board understand that the works of water supply in respect of which sanction is sought to a loan of £100,000 are not all to be undertaken at once, but will be carried out during the next five years, and that the Town Council contemplate raising the proposed loan by such instalments as may from time to time be found necessary for defraying the cost of the works executed. Under these circumstances, the Board are not prepared to sanction at once the borrowing of the whole amount of £100,000. If, however, the Town Council will amend their application by limiting it to the sum which they will require to defray the cost of works to be undertaken immediately, or in the course of the current year, and will at the same time furnish the Board with detailed estimates, and with such plans as may be necessary to explain the character and situation of the works, the Board will give the matter their consideration. The Board observe that section 26 of the Birmingham (Water) Act, 1875, provides that money borrowed under that Act after the expiration of five years from the date of its passing shall be repaid within 90 years after the borrowing is effected. The Board would not be disposed to authorize a loan for so long a period in respect of such works as appear to be contemplated in the present instance; and their sanction to any borrowing under the Local Act would only be given on an undertaking from the Town Council to repay the money within such period as the Board should determine." This reply was very unsatisfactory to the Committee, both because it seemed to imply that at every stage, before any part of the contemplated works could be undertaken, a separate application to the Local Government Board would be necessary, and also because the shortening of the period for repayment of the loan would cause an increased burden on the annual revenue of the department. It was therefore thought desirable to make an attempt to induce the Board to reconsider their decision; and communications were thereupon opened with their officers with this view. The result of these communications has been that the Committee have been informed that, having regard to the nature of the contemplated works, the Board decline to consent to a loan the repayment of which is to extend over a period longer than 30 years; but that on the understanding that the period will be thus restricted, the Board will be prepared to sanction the borrowing of a sum of £50,000 to cover the cost of those works the necessity for which is most pressing. The Committee have further considered the new works it will be necessary to undertake shortly, all of which were included in the statement submitted to the Council on the 7th of February last. It will be remembered that an extension of mains to Acoc's Green and Solihull was among the objects enumerated. It has been found desirable to deal with the supply of both these important districts without delay. In the case of Acoc's Green, the Committee have authorized such extension to be made from Coventry Road by a 6-inch main, at an estimated cost of £720. It being necessary to carry the main across the Great Western Railway, the Committee have entered into an agreement with the Railway Company for enabling them to use the bridge close to Acoc's Green Station for this purpose. With reference to the case of Solihull, the Committee received a memorial signed by 52 occupiers of houses in and adjoining that town, asking for the mains to be carried there; and, after full consideration, the Committee have decided, subject to the approval of the Council, to continue a 9-inch main from Acoc's Green to Solihull, at an estimated cost of £3451. The Committee have every reason to anticipate that a remunerative rental will be received in consequence of the inclusion of these districts within the area of supply.

LEICESTER CORPORATION WATER SUPPLY.

HALF-YEARLY REPORT OF THE WATER COMMITTEE.

At the Meeting of the Leicester Town Council last Tuesday—the Mayor (Mr. T. Wright) in the chair—the report of the Water Committee for the six months ending June 30 last was presented. It showed that the net profit on the water undertaking of the Corporation for this period was £5620 5s. 8d., out of which £1961 had been paid to the sinking fund; leaving a net balance of £3659 5s. 8d.

Alderman WINTERTON, in moving the adoption of the report, remarked that, though it did not contain anything of a very striking character, he was pleased to state that during the last 15 months they had reduced the waste of water from 24 to 17 gallons per head per day; and he hoped further improvement would be effected in the same direction, seeing that they would thereby be enabled to postpone for a considerable period the large expense of providing an additional supply. Having called attention to the fact that the Thornton reservoir had been cleaned out during the year, he stated that at the commencement of the year the reservoirs were extremely low, consequent on the drought of the previous summer and the lack of rain in winter; and thus some persons were well-nigh panic-stricken lest the water supply should fall short. After paying for the clearing out of the Thornton reservoir, the Committee were able to show a balance in hand of £3659 on the half year. They could not make any concession in price, seeing that theirs was not a continuous profit like that of the gas undertaking; and, moreover, when they incurred the cost of providing an extra supply, these profits would cease, and they would have to come to the Council for assistance. Notwithstanding that they were sending out many hundred millions of gallons of water in excess of the corresponding period of last year, he was pleased to say they now had a supply which would last until next April; so they were "out of the wood" as far as any danger of running short in the future was concerned.

Mr. G. GREEN seconded the motion, and congratulated the Committee on the reduction of the waste of water to the extent mentioned by Alderman Winterton. He claimed, however, that this reduction must be extended over the last five years, and not confined simply to 15 months, as mentioned by the Chairman of the Committee.

Alderman WINTERTON pointed out that when the last application was made to Parliament for additional powers, it was based on a calculation that 24 gallons per head per day were necessary; so that the assertion just made by Mr. Green was, to say the least, very mysterious. He (Alderman Winterton) was the first to advocate in the Council the purchase of the water-works; and he had every confidence that the time and attention which he had bestowed on the undertaking would meet with reasonable recognition by the Council.

The report was adopted.

THE FINDING OF WATER AND METALS BY DIVINATION.

The publication of the particulars of the experiments recently conducted at Hastings with the view of finding water by means of the "divining-rod," to which reference was made in the *JOURNAL* last week, in connection with our own personal experience of the power of the "rod" to indicate the presence of metals beneath the soil, has aroused considerable interest as to this extraordinary property of the hazel twig. As the matter is one in which our readers are concerned, we reproduce a leading article which appeared on the subject in the *Morning Post* on Monday last week, and notice briefly some correspondence which ensued. The article was as follows:—

The use of the divining-rod has been supposed to rank among the quaint superstitions by which the credulity of the middle ages was distinguished. It will, therefore, be a surprise to the majority to find it employed for the discovery of water on the site of the new workhouse at Hastings, under the sanction, as reported, of the Committee of Guardians, who are believed also to be highly satisfied with the result of the experiments. So far, it must be admitted that these results are entirely potential, and consist merely in the confident assertion that water is to be found in several places at depths varying from 30 to 80 feet below the earth. The "diviner" came fully armed with a hazel twig, and fortified by letters of recommendation from several landowners to whom he has apparently rendered substantial service in discovering wells. The hazel twig was duly agitated at intervals; and unless it prove to be a false prophet, the inmates of the new workhouse are not likely to suffer from any lack of water.

It does not seem that this is by any means an isolated experiment, although it is seldom heard of in the south-east of England. The divining rod is still employed in Wiltshire for the purpose of detecting water. In Vol. XXII. of the *Quarterly Review*, there is an account of a well-authenticated case which was communicated to the writer of an article on "Popular Mythology." A lady of undoubted integrity is there related to have convinced Dr. Hulton that she really possessed this strange gift by the practical method of indicating the existence of a spring in a field belonging to him, the value of which was largely increased in consequence. De Quincey, as his readers will remember, affirms that he had often seen the experiment practised with success; and says that in a vale of North Somerset most of the tea-kettles are filled with rhabdomaney, whatever science may have to say to the contrary. The Guardians of Hastings, then, can claim some amount of respectable precedent for their curious proceeding, although De Quincey somewhat weakens his own advocacy by the subsequent admissions that the professors of the divining-rod were locally known as "jousers"—a word which he thinks is indisputably connected with the slang verb "to chouse." It may, of course, be that any doubt of the genuine nature of the practice did not refer to its efficacy in detecting water, but to the extravagant and palpably absurd notions which connected the divining-rod with the discovery of crime. In the middle ages, and particularly, as it would appear, in France, the "diviner" was a favourite species of police agent, and was employed by Government for the purpose of tracking criminals. The hideous injustice resulting from such a method scarcely needs to be dwelt upon. Even those people who really believed that the rod would in their hands point out a murderer were no more sure of their own powers than is the spiritualistic "medium" of to-day; and they seem to have been equally ready in feigning knowledge which they did not possess, as the preservation of more than one celebrated case clearly proves. It is true, that, once embarked on this precarious career, they could scarcely withdraw from it, and were prompted by imperious fear for their own safety to risk the lives of others. But the general consequence to society of these baneful superstitions was incalculably bad, and may have suggested the ironical advice of Montesquieu, that if a man was accused of stealing the towers of Notre Dame his best course was to fly at once.

The more enlightened people of the sixteenth and seventeenth centuries strenuously denied the possession of these inquisitorial powers to the divining-rod. Many of them were equally incredulous as to its having the relatively harmless faculty of detecting metals beneath the earth's surface. Indeed, from classical times there has been a decided disposition to laugh at this pretension, which, in the absence of any witness who has attained a fortune by its means, is not wholly unaccountable. In the days of Ennius, the art could be thoroughly acquired at the moderate cost of one drachm, although, *ex hypothesi*, it would have been infinitely more lucrative to keep such knowledge secret. The same thing, however, might obviously be said concerning the "tipster" of to-day's racing world, who appears gifted with the power of making everyone's fortune but his own. In the famous treatise on metals, Agricola is very severe on the workmen who used divining-rods, declaring that it was an old magical practice only to be tolerated by the "irreligious." The Cornish miners are still often accused of using the hazel twig to discover metals; but all the patient research of Mr. Baring-Gould, whose familiarity with the West is well known, failed to discover any really authenticated instance of this usage, all knowledge of which was repudiated by the mining captains who were questioned. In fact, the fallacious character of this use of the divining-rod is much more easy of detection than the others. There was a sort of glamour attaching itself to the criminal investigations, which appears to have blinded even worthy and intelligent people to their demoralizing character. On the other hand, men do not by any means invariably dig for water because a hazel twig showed symptoms of agitation at a certain point. At any rate, if the good folk at Hastings are going to dig a well in every part of their plentifully watered field indicated by the "diviner," the occupants of the future workhouse will run a distinct risk of getting drowned. It may be doubted, however, whether anyone who believed in the attraction of the precious metals for the divining-rod did not make some furtive attempt to pry below the surface literally as well as metaphorically. In that case, repeated disappointments have brought wisdom; and the efficacy of the rod is now held to apply chiefly to cases where it is desired to discover a well. The results at Hastings will be somewhat curiously watched by a generation which is disposed to regard the entire proceeding with a languid amusement rather than with any stronger feeling.

To the student of comparative history, however, the survival of such a practice in a flourishing English town at the end of the nineteenth century cannot fail to be a matter of keen interest. The rod has in all religions and in all mythologies alike been the symbol of strength and authority. Its Biblical use in the hands of Moses and Aaron, and its subsequent profanation by the chosen people, need not be commented on. It seems that rhabdomaney was a familiar form of divination among the Greeks; while Cicero speaks of it as equally practised by the Romans, and Tacitus found traces of its use even among the ancient Germans. With the solitary exception of its supposed efficacy in indicating water, the superstitions which attached to it have been swept away. Whether there is some grain of truth in this magnetic connection between wood and water in the hands of certain ultra-sensitive persons, is likely to be a disputed question. Science may detect impostures by the score; but experience has an awkward trick of confounding it with instances where every desired condition seems fulfilled. At a levity, if the latest "diviner"

proves to be entirely correct, a certain amount of interest will be raised in the question. This will take the form of elaborate disquisitions and scientific refutations well calculated to make the Hastings Guardians doubt whether life is worth living—at least as a rhabdomicist. If some "diviner" had arisen in time to let building contractors and architects into the secret of the watery condition of the subsoil in more than one lately opened-out part of London, a good deal of labour and capital would have been saved. If rhabdomaney is again to become one of the learned professions, it will at least be desirable that its exponents have a correct estimate of the value of mixing the useful with the phenomenal.

Referring to some of the statements contained in the preceding article, a lady wrote as follows:—"I have studied many writers on chiromancy, astrology, &c., for some years, and have found references to what you term 'rhabdomaney' (also called corilimancy), explaining that to be successful in discovering treasures in the earth the branch of hazel must be gathered astrologically, and be chosen of a forked shape, either like a γ or a Greek *upsilon*, and that this mark should be likewise found in the hands of the person using it. Should the result of a modern test be satisfactory, I should esteem it a favour if Mr. Mullins (or anyone interested at Hastings) would give further details of the rod, and examine his hands minutely." Mr. E. Hales, who about two years employed Mr. Mullins to exercise his powers on an estate near Tonbridge, states that he was successful in finding water in several places. Mr. Hales says: "My daughter, who accompanied us, was very suspicious. Mullins, therefore, invited her and one of my servants each to grasp the two ends of the hazel twig, which was forked and about 2 feet long, and which he held dear the fork with his thumbs and fingers, and when he passed over the spots where the water ran, the twig was so violently agitated that it bent until it broke in their hands; and this I saw myself. Mullins is a working man without any pretensions; and he says that very few persons possess this faculty, and that after a few hours' exploring it takes a good deal out of him. Mr. Hales adds that Mr. Mullins's power only extends to running water. The Rev. H. P. Gurney, Vicar of Uffington, in Berkshire, states that he remembers, when a boy, accompanying a number of adventurers over several fields on his father's estate in Cornwall, and seeing them use the divining-rod for the purpose of discovering metals. The result was that a company was formed and the mineral rights on the estate bought of his father and a mine commenced. It was worked for two or three years, but was then abandoned. He adds: "I think several people might still be found in Cornwall ready to venture their money on the indications of the divining-rod." Mr. J. Stears, of Hull, whose power as a "diviner" of metals we recently witnessed at Lisburn, as recorded last week, says: "Those who have not seen the rod in use laugh at the idea. After using the rod for 19 years successfully in finding both iron pipes and underground streams of water, I may venture to reply to your article. It seems that only a few persons are able to use the rod; and with most of those who have the power, it only turns for water, and not for metals. I can find both. For water, the rod, which is Y-shaped, turns from me until the point of the twig which was downward turns; but when over metal, such as gas-pipes, the rod turns towards the body, and then rises up when exactly over the pipe. If I stand upon two china dishes, all power is lost; thus showing the power to be electrical, and must have an earth connection. Much has been written on the subject, but always by those who cannot use the rod."

THE NEW WATER SUPPLY AT SALTASH.—A quarter of a century having elapsed since the Saltash Town Council first took up the question of providing the town with a pure and constant water supply, it is satisfactory to find that in less than six months the inhabitants will have their wishes in this respect gratified. It was left to the present Council to push the matter forward; and a supply having been secured, an engineer has been appointed to carry out the work. At a meeting of the Town Council last Thursday, it was reported by the Mayor (Mr. G. Adams), as Chairman of the Water Committee, that provisional terms had been arranged with the owners of the land at the source of the supply. The Engineer (Mr. B. Nicholls, C.E., of Birmingham) has just been to Saltash, and is preparing plans, which will be ready in three weeks to submit to the Local Government Board. The works are expected to take about six months to carry out; so that, under favourable circumstances, the water should be flowing into the town by June next.

THE PROPOSED EXTENSION OF THE BURNLEY GAS-WORKS.—Mr. A. Taylor, one of the Local Government Board Inspectors, opened an inquiry at Burnley last Wednesday in regard to an application made by the Town Council of the borough to borrow £8500 for the extension of the gas-works. Mr. Jas. Emmett (a ratepayer) intimated at the opening of the proceedings that he opposed the application. The Town Clerk (Mr. W. Southern) stated that he had sent to the Local Government Board a statement showing the purposes for which the money was wanted. The Gas Engineer and Manager (Mr. S. P. Leather) spoke as to the development of the gas-works. He said that ten years ago the quantity of gas made was 167 million cubic feet, and that last year it had risen to 310 millions. He also submitted a plan of the new works. Mr. Emmett pointed out that upwards of £3000 had been handed over from the Gas Department to the borough fund during the past twelve months, and still they were going on borrowing. The Inspector said he had nothing to do with that. He always understood that the Corporation could not make extensions out of the gas profits, but that these must be carried to the credit of the general district rate. Mr. Emmett desired to draw attention to the rating of the borough, but was ruled out of order, and after some further discussion the inquiry closed.

SALES OF SHARES.—At a recent sale, by Messrs. G. Tinker and Son, at the Rose and Crown Inn, Longwood, 18 fully-paid £10 shares in the *Longwood Gas Company* (offered in four lots) realized £19 and £19 1s. per share respectively. Subsequently, 20 similar shares were put up in four lots, and realized £19 and £18 17s. 6d. per share.—On Monday last week, Mr. J. C. Towner sold by auction, at the Gildridge Hotel, Eastbourne, 50 original £10 shares, 39 "B" £10 shares, and 28 "C" £10 shares in the *Eastbourne Gas Company*. The first-named shares were sold at prices ranging from £26 2s. 6d. to £26 10s. each; the "B" shares fetched £19 10s. and £19 17s. 6d. each; and the "C" shares, £25 and £26 2s. 6d.—On the same day, Mr. H. C. Walton sold £1960 of stock in the *Preston Gas Company*, bearing a maximum 10 per cent. dividend, in lots of £100 each. The stock realized an average of £222 per lot.—Messrs. Nicholson, Greaves, and Barber sold last Tuesday at Sheffield, £30 consolidated "B" stock in the *Sheffield Gas Company*, for £91; being at the rate of 303 per cent.—Last Wednesday, Messrs. Renton and Renton sold by auction, at Harrogate, £2000 of "B" stock in the *Harrogate Gas Company*. It was offered in £100 lots, and included the dividend (at the rate of 1½ per cent.) accrued since July 1 last. The 20 lots were knocked down at the following prices:—Four at £241; four at £242; ten at £243; and two at £244—total, £4850, being an average of £242 10s. per lot. The stock was eagerly sought for—the attendance of buyers being large; and the whole was disposed of in about half an hour. The purchasers will receive £4 12s. 9d. per cent. on their investments.

NOTES FROM SCOTLAND.
(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.

The Edinburgh and Leith Gas Commissioners had before them on Monday the heaviest item of business which they have yet encountered since they took over the gas supply, in the shape of a proposal by Mr. Mitchell, the Engineer of the Edinburgh works, to improve the carbonizing department, at a cost of £20,000. I suppose I am safe in saying that the disparity of the cost of production in the two works of the Commissioners has forced them to the conclusion that something must be done to modernize the Edinburgh works, in order to get better results from them. The Company were fully aware of the necessity for a step in this direction. Their Bill of two years ago, empowering them to remove their works to Niddrie, is sufficient testimony to that being the case; and the prescience of the Directors would by this time have been bearing fruit, had not the negotiations for a transfer supervened. If the Company's Bill had passed, the erection of the new works was to have been begun at once; and for that everything was in preparation—Mr. Mitchell, in particular, having ready a set of plans for a most complete works on a scale of magnificence that would have been worthy of the position which the Company held among the gas undertakings in the United Kingdom. Mr. Mitchell's aspirations were not then realized; the old works must suffice in the meantime, and accordingly he comes forward with a proposal to improve them by a judicious outlay. The Commissioners sent the matter to the Works Committee for consideration; and this body had it under discussion yesterday. No decision has been arrived at yet. I cannot tell why; but I should not wonder if some of the Commissioners find it a bitter pill, after all the fine things that were said of the Edinburgh Company, to have it even hinted so soon that a large outlay like that contemplated would be desirable.

The work of winding up the two Gas Companies in Edinburgh and Leith has been proceeding apace under the direction of the officials of the Companies, who, though in the employ of the Commissioners, have remained also in their former situations with the Companies for the purpose of carrying out the winding up. The process of "settling up" has included the recovery of rental from many consumers by summons in the Small Debts Courts. These and other processes of a more pleasant nature have been so far completed that a meeting of the shareholders of the Edinburgh Company to receive a statement of the funds of the Company, and give instructions as to their distribution, has been called.

The movement which I mentioned last week as being on foot in the direction of transferring the St. Andrews Gas Company's undertaking to the Corporation took definite shape at a meeting of the Town Council on Tuesday. One is inclined, after what was said, to cherish the wish that, before seeking to assume control of the gas supply, the members of the Council should have a clearer conception of what their future duties would be, than they seem to have. For instance, Provost Paterson, in proposing a motion that it was expedient to adopt the Burghs Gas Supply Act, instead of showing how St. Andrews would be affected by the transfer, must needs wander away to Manchester, with which, in passing, I may say, there could be no comparison whatever; and from there began to dangle before the community that most questionable of all practices in Corporation gas management—the plundering of the gas profits to save the rates. Of course, he displayed his bait more cunningly than I have just expressed it. The words he used were: "The results would be such as to astonish the ratepayers. In Manchester, for example, they had been able to pay a large proportion of the rates out of the unestimated profits of the gas-works." A day may come when public men will be found managing the gas industry in its own interest; but it is manifest that before then a good deal of education will have to be undertaken in high places. The Provost thought that the gas undertaking could be purchased for £10,000. Another member of the Council was afraid that, looking to the large dividends which had been paid by the Company, the price could not be less than £20,000. These and one or two other remarks were quite legitimate; and there was a prospect of the discussion closing before the speakers descended to foolish talking. But that was not to be. The inevitable nonsense about the electric light was duly "trotted out." Mr. G. Bruce, who was responsible for its introduction, I am afraid does not read the "Electric Lighting Memoranda" in the JOURNAL, or he would not have inflicted on the Council his gabble about the electric light making "rapid progress." "Were they," he asked, "to be condemned to burn gas for the next 40 years, when they might have a better and cheaper light within a very few years?" Judging from the experience of other towns in electric lighting, one is tempted to say that the condemnation which Mr. Bruce so much dreads is likely to be the opposite of the very terrible affair which he contemplates it will be. Apart from every other consideration, there is one test by which, as much as by anything else, the prospective stability of gas supply may be gauged, and that is that there is not yet, to my knowledge, a single instance on record in which a gas company took the initiative in the matter of having its property transferred to a local authority. From this it would appear that inside the gas industry there is not so much fear of loss as there is outside it. The St. Andrew's Town Council seemed to be a good deal affected by the arguments of the opposition, as, though the motion was but a preliminary one, they only adopted it by 12 votes to 9.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.

The Dumbarton Corporation have lately agreed to take £300 from the gas profits of the past year, for the purpose of meeting the expenditure involved in connection with the Public Parks. From year to year the deficiency in the income derived from the Clyde Pier has been met out of the gas profits; but this is the first time that it has been necessary to subsidize the Public Parks from the same source. The past year's working of the gas undertaking was very successful. There was a considerable increase in the consumption of gas; but the returns show that it was still very much behind that of the last year of good trade—1884-85.

It has been resolved by the Gas Committee of the Ardrossan Police Commission to continue the price of gas unchanged for the present year, notwithstanding the fact that there was a surplus of income over expenditure for the past year quite sufficient to warrant a reduction. It has been editorially suggested in one of the local newspapers that the ratepayers will in their own interest take the matter up, and that if they are unable to bring about a reduction in the gas-rate, should at least insist on knowing the reason why. It is urged that there has been a reduction in the price of coal, and that there is an advance in the value of the residuals; and consequently the Gas Committee must have in view a much larger surplus at the close of the current year. The increase to the Commissioners from the residuals is said to be fully 50 per cent.; and when the gas supply was in the hands of the private Company, the value of the residuals was about one-fourteenth part of the cost of production, whereas it is now about one-tenth. The writer affirms that, without any risk of lessening the benefit to posterity, the price of gas in Ardrossan might have been fixed at 3s. 11d. per 1000 cubic feet for the year 1888-9. The question of

the perpetual meter-rent, which is said to be very unfair, is also engaging attention; and it is suggested that this burden should be removed.

The Glasgow Corporation Gas Committee have lately had under consideration an offer from Messrs. C. McNaught and Co. for the purchase of the whole of the output of coke at their various gas-works; but it has been resolved to decline to entertain the offer, there being a marked unwillingness on the part of the Committee to disregard the claims of local consumers generally, and especially the claims of the poor people near the works, who use the coke as their ordinary fuel. While speaking of Glasgow gas affairs, it may be worth while to mention that already there has been recovered fully £4000 more than the amount estimated of the outstanding gas-rents referred to in the last annual balance-sheet. The estimate was £43,688; the amount recovered is well nigh £48,000.

At the recent sitting of the Argyllshire Valuation Appeal Court, the Dunoon Police Commissioners appealed against the valuation of the burgh water-works, which had been increased from £400 to £800. The question was argued at some length on behalf of the appellants and by the Assessor; and eventually the sum fixed was £700. At the same Court, the Assessor's valuation of the Sandbank Water-Works, which had been increased from £126 to £220 was appealed against; it was reduced to £200.

The Glasgow pig iron market was somewhat unsettled during most of this week. In consequence of "bears" operating, considerable reductions in price took place. The volume of trade, however, continues to be exceedingly satisfactory; and on this account, it is not anticipated that there can be any extensive fall in price in the meantime. Scotch warrants were sold on Monday at 42s. 0½d. cash per ton; and yesterday 41s. 4½d. cash was accepted. The fall in the price of Cleveland warrants was from 34s. 11d. to 34s. 3d. per ton; and the prices of hematite iron declined from 45s. 3d. to 44s. 1½d. per ton.

Freight rates being somewhat easier, the local coal trade has been less firm this week; but a good business has been done, and the trade looks very promising. Prices are advancing in most departments; indeed, household coal is about to be increased in price 1s. per ton. It is not unlikely that the miners' wages will be generally raised within the next week or two.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Sept. 29.

Sulphate of Ammonia.—The week closes with a strong tone, due mainly to the large French orders which are unexpectedly coming in; and while requirements in that country remain to be filled, it may be taken for granted that prices on this side will not suffer, although it is anticipated by dealers that values will be easier next week. To-day £11 10s., f.o.b. Hull, is being readily paid for shipment; but meanwhile buyers decline to pay the same price for early October delivery. In consequence of the very firm tone of nitrate, there is considerable inquiry for spring delivery, and buyers are willing to pay full rates. Producers have, however, meanwhile assumed a passive attitude.

LONDON, Sept. 29.

Tar Products.—The prices current last week are those ruling at present. The feeling in anthracene, pitch, and carbolic has, if anything, a firmer tendency. Prices: Tar, according to position, 17s. 6d. to 22s. 6d. per ton. Benzol, 90 per cent., 3s. per gallon; 50 per cent., 2s. 4½d. Toluol, 1s. 9d. per gallon. Solvent naphtha, 1s. 2d. per gallon. Creosote naphtha, 30 per cent., 1s. per gallon. Light oil, 3d. per gallon. Creosote, 2d. per gallon. Pitch, 12s. to 13s. 6d. per ton. Carbolic acid (crude), 3s. 4d. per gallon. Cresylic acid, 9d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 6d. per unit; "B" quality, 1s. 3d.

Ammonia Products.—Sulphate of ammonia is steady, at a slightly improved price. Prices may be taken as follows:—Sulphate of ammonia, £11 10s. to £11 12s. 6d., less discount. Gas liquor (5° Twaddell), 7s. 6d. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 1½d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £27. Sal-ammoniac, £30 per ton.

[From the Chemical Trade Journal, Sept. 29.]

Sulphate of Ammonia.—The sulphate market is firm for prompt delivery, in consequence of a good demand from France; and prices at Hull have advanced from £11 7s. 6d. and £11 8s. 9d. to £11 10s. to-day. These prices can, however, only be realized for parcels that can be shipped this week. The dealers seem to be all more or less short, and apparently have much difficulty in completing their deliveries this month. Liverpool is quoted at £11 7s. 6d. to £11 10s.; Leith, at £11 8s. 9d.; Beekton, £11 10s.; while London outside makes are fetching from £11 10s. to £11 11s. 3d.

Tar Products.—Benzoles remain without sensible alteration in price; and even the short production of the past few months does not seem to have improved the situation. 90's and 50/90's may be stated as having the same value as described in last week's circular; and all other tar products remain *in statu quo*. The unfinished products, as we may term them, keep up their price; and there is still a very fair business doing in medium soft pitch. Benzole from coke-ovens is the latest information which comes to our ears, as from properly constructed ovens as much as 2 gallons per ton of coal has been obtained on the large scale.

ANTWERP WATER COMPANY, LIMITED.—The Directors of this Company, in their half-yearly report to June 30 last, state that the income from all sources amounted to £10,036, and the net revenue to £4248. Should the profit arising from the second half-year's working be equal to the present, there will, it is stated, be sufficient to pay an increased dividend on last year. The 5 per cent. debentures, amounting to £13,000, falling due on Dec. 31 last, will be renewed at 4 per cent.

BARNET IN DARKNESS AGAIN.—At ten o'clock last Friday night the electric lamps at Barnet suddenly went out, and the streets were left in darkness; the only light to be seen being that coming from the windows of hotels and private houses. The night was very dark and somewhat foggy; and the inconvenience caused to pedestrians by the sudden deprivation of light was severely felt. The origin of the mishap was not known outside the electric light works, beyond the scanty information vouchsafed by one of the contractor's employees that something was wrong with the engine. It was not until midnight the light was again available.

THE GAS AND WATER UNDERTAKINGS OF THE BIRKENHEAD CORPORATION.—The Birkenhead Corporation propose applying to Parliament next session for additional powers, and the opportunity will be taken to obtain authority for the purchase of land for the extension of the gas-works. As the attention of the Gas and Water Committee has been called to the fact that the period within which the new water-works authorized to be constructed by the Birkenhead Corporation (Gas and Water) Act, 1881, will expire on Jan. 1, 1892, the Committee have resolved that it will be desirable that an extension of time for the construction of the works shall also be obtained.

REDUCTION IN PRICE.—The Directors of the *Biddulph, Bradley Green, and Black Bull Gas Company* have reduced the price of gas from 5s. to 4s. 6d. per 1000 cubic feet, and will allow a discount of 5 per cent. on all accounts paid within a month.

CORSHAM (WILTS.) WATER SUPPLY.—A Company has just been formed to provide the town of Corsham, in Wiltshire, with a constant supply of water. The capital is £4000, in £5 shares. It is proposed to bring the water from Ash Hill and Ash Grove, near Bowood, on the estate of the Marquis of Lansdowne; and, owing to the elevated springs, the water will be carried through the pipes by gravitation alone.

SCARCITY OF WATER AT CHESHUNT.—Complaints are being made of the scarcity of water at Cheshunt, High Beech, and Waltham. At a meeting of the Waltham Local Board last week, it was stated that, owing to the East London Water Company having sunk wells in the neighbourhood, to meet the requirements of part of their district, the supply of East Herts had diminished. It was resolved to communicate with the Company on the subject.

THE LIVERSEDGE LOCAL BOARD AND THE WATER QUESTION.—The Local Government Board have intimated that they will not at present sanction the payment of the costs incurred by the Liversedge Local Board in connection with their proposal to apply to Parliament last November for independent powers of water supply. The head authority says that the accounts must go before the auditor in due course, and that any further communication that may be received will then be considered. An application was made by the Clerk to the Board some time ago; and it is understood that the refusal is in consequence of letters addressed to the Local Government Board by representatives of opponents of the scheme.

THE PROPOSED PUBLIC LIGHTING OF GRAVESEND WITH OIL.—At a meeting of the Gravesend Town Council held last Wednesday, the Town Clerk reported that a difficulty had arisen in arranging the terms of the contract with the firm who had tendered for lighting the public lamps of Gravesend with oil. The Corporation considered that the contractors should remove the present burners and plug the pipes so as to prepare the lanterns for the reception of the oil lamps. The other parties took an opposite view; contending that they had only to make the lanterns wind proof. From this view they declined to give way; and, after some discussion, the Corporation decided not to execute the contract.

WEST GLOUCESTERSHIRE WATER COMPANY.—At the half-yearly meeting of this Company held at Bristol last Saturday, the Chairman (Mr. A. Brogden) stated that since the previous meeting 350 additional houses had been supplied with the Company's water, and that there was every prospect of a steady increase in the number of customers. Nine miles of additional mains had been laid in the half year, for supplying populous places within the Company's district, including Warmley and Keynsham. The number of houses now within reach of the Company's mains was 2300, one-fourth of which the Company were supplying. The revenue had overtaken the working expenses, and for a new Company their position was very encouraging. At no distant date the shareholders might expect a dividend. The Directors' report was unanimously adopted.

THE WELL AT THE CLAPHAM WORKHOUSE.—The Guardians of the Wandsworth and Clapham Union appear to be somewhat out of conceit with their attempt to provide their own water supply. At their fortnightly meeting last Thursday, the Chairman announced that there was no water that morning for domestic use in the house. He believed there was water in the well, but it appeared the action of the pumps was so violent that it exhausted the well too quickly. As to the Water Company's mains, the pressure was so small that the supply from this source was intermittent. He thought that if they had an engine to pump at a reduced speed, they could get a supply day and night. A discussion arose upon these statements. Mr. Plumridge protested that it was nonsense to attribute a short supply to want of pressure in the Company's main. The pressure was enough to burst the pipes; but the water was shut off in the house. The fact was the well was a failure, and would not yield the 24,000 gallons a day which it was stated it would do. He submitted that it would be cheaper to obtain the whole supply from the Water Company, and do away with the well. Mr. Grey concurred with this view, and declared he would not vote for any more expenditure on the well. A motion was submitted to refer the matter to a Special Committee; but in the end it was sent to the Workhouse Committee for consideration.

GWYNNE & BEALE'S PATENT GAS EXHAUSTERS AND ENGINES

PLEASE ADDRESS IN FULL—**GWYNNE & CO.,**
HYDRAULIC AND GAS ENGINEERS, ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C., ENGLAND.
TELEPHONE No. 2698.

Address for TELEGRAMS:
"GWYNNEGRAM LONDON."

Thirty-three Medals at all the Great International Exhibitions have been awarded to GWYNNE & Co. for Gas Exhausters, &c.

Only Medal at the Liverpool International Exhibition, 1886, for Centrifugal Pumping Engines.

They have never sought to make price the chief consideration, but to produce Machinery of the very highest quality.

The result is that in every instance their work is giving the fullest satisfaction.

They have completed Exhausters to the extent of 24,000,000 cubic feet passed per hour, which are giving unqualified satisfaction in work, and can be referred to.

ONLY 75 REVOLUTIONS PER MINUTE.

The above Engraving shows Two Engines driving Four GWYNNE & CO.'S PATENT NON-FLUCTUATING GAS EXHAUSTERS, to pass 200,000 cubic feet per hour (without the slightest oscillation), at the EFFINGHAM STREET GAS-WORKS, SIEFFIELD.

Can be made, when desired, on their New Patent principle to pass Gas without the slightest oscillation or variation in pressure.

NO OTHER MAKER CAN DO THIS.

GAS VALVES, VACUUM GOVERNORS, REGULATORS, PUMPS, &c., &c.

Catalogues and Testimonials on application at the above address.

GAS LIGHTING AND PUBLIC SECURITY.

THE connection between gas lighting and the progress of civilization is a subject worthy of the closest study of the sociologist. Most readers of Herbert Spencer's interesting "Introduction to the Study of Sociology" will remember what magnificent use the writer makes of one of the great facts of modern civilization—the printing of *The Times*—the full significance of which we are apt to overlook because the phenomenon is so common and familiar. If a similar book were to be written by the same philosopher (which is too much to expect), what splendid service he might evoke in the way of exposition from the common spectacle of a street gas-lamp! It is remarkable that one of the earliest popular notices of gas lighting that has come down to us, is in the form of a coloured print, of the kind whereby the caricaturists

and pictorial satirists of the early part of the century used to register the public sentiment of their day, in which the artist anticipates in the clearest fashion the probable purifying effect of improved lighting upon the morals of the streets. The footpad and the strange woman are in this picture represented as fleeing from the new light into regions of obscurity more favourable to their proceedings. Wherever gas lighting has penetrated, the authorities responsible for the preservation of order and the prevention of crime in cities have recognized that a gas-lamp is as good as a policeman—and sometimes considerably better. It is not too much to say that the striking difference in the condition of the streets of our towns, as regards the safety of wayfarers, which marks the present as compared with the age whose manners are described by Fielding and caricatured by Rowlandson, is due quite as much to gas lighting as to the institution of the modern police force. There is at least as close a connection between the two agencies for promoting order as between the originator of the penny postage and the railways which rendered this reform practicable. If Stephenson had not gone before, Rowland Hill could not have carried out his great scheme; and, similarly, if Murdoch had not preceded him, Sir Robert Peel would have organized his police force with infinitely greater difficulty and much less success. The gas-lamp and the policeman are twin forces that have worked in harmony to redeem the streets of our towns from the riot and savagery which we can hardly realize when we read about them in old story-books, and should not endure for a week if the condition could be repeated in a truly realistic revival of an "Old London" or an "Ancient Glasgow." It is interesting to see the picturesque street architecture of those times reproduced for our amusement at national exhibitions; but we are rightly content with the revival as a mere piece of scene painting. We fall back from contemplating the past with a sense of satisfaction (not less deep or real for being unexpressed and almost unconscious), upon the reflection that we can walk through our modern streets without requiring the attendance of link boys and armed servants, thanks to the unpicturesque gas-lamp and prosaic police officer.

These reflections spring naturally from events that are passing round us to-day. During the last few weeks London, and through London the whole country, has been thrilled by the recurrence, in a ghastly series, of horrible street outrages that have revealed the gulf of savagery over which our boasted civilization has been thinly stretched. Decent people, while perusing with the fascination of utter horror and disgust the published accounts of the recent Whitechapel murders, have shrunk appalled from the revelation of this survival into their midst of passions and practices which they have believed to belong to a past age and a barbarous society. It would be near the truth to say that, having regard to the peculiar circumstances of these crimes, the general sentiment of the mass of the people respecting them has not been fear so much as shame and horror. The least thoughtful among us must have allowed his mind to dwell for an instant, with heart-shaking doubt respecting the soundness of our civilization, upon the reflection that in walking through the streets one may rub shoulders with beings whom the very Goths that sacked Rome would have condemned as inhuman. It comes as a shock—and in one sense not perhaps an unnecessary or undesirable one—to the somewhat "namby-pamby" humanitarianism of the day, which is often theoretically disposed to side with the mob against the forces of law, when it is shown, by such examples as these slaughterings in the streets of London, that primeval savagery remains among us still, and would break out if it had the chance. Why is it, however, that this sentiment of horror is so little mixed with fear? For the simple reason that the exemplar of the horrible propensities of men who are untouched by ordinary human feelings has shown a reassuring respect for the arm of law and the light of civilization. He has kept out of sight of the policeman, and beyond the radius lighted by the street-lamp. The Chief Commissioner of Police for the Metropolis has replied to the Whitechapel Vestry, who tried to bring him and his men into blame for permitting this outbreak of crime in their district, to the effect that the Vestry themselves are in a measure responsible for creating the conditions by which the crimes have been rendered possible, through neglecting to light the bye-streets and no-thoroughfares of the parish. This modern instance places in the strongest possible light the efficacy of the street-lamp as a preventive of crime; and it is to be hoped that Sir Charles Warren's reproof will be taken to heart by other highway

authorities who, like the Whitechapel Vestry, have neglected this part of their duty to the public, but have not yet received so lurid an illustration of the dangers of such neglect.

We have never lost a fitting opportunity for reminding local authorities that the responsibility thrown upon them for lighting their towns is not discharged by making a brilliant promenade or two in the best parts, and starving the back quarters. Yet who does not know that this is a general failing of local authorities? Hear the average town councillor talk about the necessity for well lighting the town, in order that it may appear to good advantage in the eyes of residents and visitors, and ask him what he means. It will be found that his mind is set upon brightening up the High Street, or the Parade, or the neighbourhood of the Council Chamber, and that he never thinks about the back slums where crime lurks beyond the reach of the policeman's lantern. The enterprising and public-spirited gentleman who moves heaven and earth to introduce electric lighting into his native town, is usually quite content that the contractor should string his staring lamps along the main thoroughfares; and that the lighting—save the mark!—of the smaller streets should, by way of balance, be entrusted to miserable oil-lamps. We do not hesitate to declare that one outrage of the Whitechapel stamp in any town so mismanaged in the matter of lighting would form a wonderful stimulus to the local appreciation of the rights and wrongs of public street lighting. Take the recent example of Birmingham, where the lighting of the courts and blind alleys of the town has been so long under discussion. Would not the question have received a speedier solution if the Whitechapel fiend had commenced operations in these obscure localities? Yet what was there to prevent him?

One is quite justified in trying to extract good from the worst evils; and therefore we insist upon the importance of these Whitechapel outrages as illustrating an aspect of public lighting which is too apt to be overlooked. Many people have come to regard street-lamps as ornaments to a town, or at least as very much in the nature of a luxury. While admitting that the matter has this luxurious aspect, and going even further for the purpose of conceding that handsome streets in a prosperous modern town ought to be lit in a style befitting their daylight appearance, we must contend for the police use of lamps. Highway authorities may beautify the chief street promenades of their town to their hearts' content, whether their motive be municipal vanity, solicitude for shopkeepers' interests, or the honest desire to see their town look well by night as by day. There is no danger of British towns authorities being too extravagant in this way, seeing how far the majority of them fall below the practice of Continental municipalities, who, with poorer and dearer gas, manage to keep up an air of brilliancy in their boulevards which few English towns can rival. Beyond this solicitude for appearance and profit, however, comes the interest of public safety, morality, and order. Is that town the worthier that has the more gorgeous boulevards, or hides the fewer slums? This is one of the great questions of the age. London is a vast Metropolis, and to it flow the best and the worst that humanity can show. All towns in their degree possess the same power of attraction. What responsibility, therefore, falls upon the authorities charged with the surveillance of these places, to see that the ever-present criminal shall not find any facility in his designs from the parsimony and neglect of the powers constituted in the interest of the well-disposed population!

THE COMMERCIAL GAS COMPANY'S MEETING—MR. H. E. JONES'S HINTS FROM AMERICA.

THE half-yearly general meeting of the Commercial Gas Company was held last Friday, when the report and accounts were received and adopted, and the very noteworthy dividends of 13 $\frac{3}{4}$ and 10 $\frac{3}{4}$ per cent. declared. As the Chairman (Mr. R. Bradshaw) remarked, the accounts in question were among the most satisfactory ever presented to the proprietors, who have the best of all reasons to be pleased with their investment, and to be gratified at the progress of the undertaking. Mr. Bradshaw was in fairly good health; but his strength was not such as to permit him to indulge in a long speech. The Commercial shareholders are not exacting in this respect, however; while the Board continues to return such handsome dividends, the proprietors will not demand oratory at the ordinary meetings. It is only chairmen of unprosperous concerns that need be eloquent. An interesting feature of the meeting was the reference made by the Company's Engineer (Mr. H. E. Jones) to his recent tour in the United States, and his subsequent remarks respecting his impressions. As soon as

Mr. Jones stated where he had been, there was a request preferred from the body of the hall that he would tell what he thought about electric lighting in America; and this he did in a few memorable words. We shall not spoil the effect of Mr. Jones's remarks by paraphrasing them here, as they may be perused in full in our report of the proceedings of the meeting. He succeeded in convincing his hearers that even in the United States gas has nothing to fear from the electric light, but should rather be grateful to it for creating and spreading a demand for abundance of light. Gas engineers will be interested to hear what Mr. Jones had to say about the oil-gas processes in vogue across the Atlantic, especially as he arouses curiosity by his way of referring to some of these systems of gas making, without allaying it. We have some reason to believe, however, that Mr. Jones was greatly struck by the capacity exhibited by certain of these processes for producing great volumes of gas, in a very short time, from generators which, while they occupy very little space, are cheap to construct and maintain. We understand that he is rather inclined to think—but upon this point we should prefer to have further and more definite information—that, by the use of generators of this class, gasifying coke, and carburetting the product either with tar-oils or low-priced mineral oils, the present disproportion between the winter and summer gas-making plant in most British gas-works might be reduced. For winter reserves everywhere generators of this order might render valuable service. It is a novel and striking idea, which it is to be hoped may be enlarged upon by Mr. Jones on some future occasion. Altogether, the Commercial Gas Company's meeting was well worth attending.

A CASE FOR SYMPATHY.

ONE regrettable result of recent scandals, and the attempts made in certain quarters to trade upon them, has been the creation of a very widespread feeling of suspicion and distrust. In theory, every man is innocent until proved guilty. In practice, the reverse of this is the accepted doctrine of the day; and any story impugning the honesty of those concerned in gas-works administration—however ridiculous it may appear to those who know the real facts of the case—is sure to be eagerly swallowed, and readily believed, by those less well informed. As a proof of this it is only necessary to call attention to what has been taking place at Rochdale within the past few weeks. In that borough, as elsewhere, the stormy period of agitation which precedes the annual municipal elections has just begun, and a number of eager spirits who know, or think they know, of a short cut to a local millennium, have been inveighing against the powers that be, in order to prove how much better they could themselves manage if only they had the opportunity. One of the points of attack was the Gas Committee—who have given mortal offence by presuming to increase one or two salaries—and one of the charges against them was that they negligently, if not fraudulently, accepted a tender for coal at 1s. per ton more than they need have paid for the same article. The statement was made with some circumstance at a public meeting; and "a member of the Gas Committee" was cited as the authority for it. So serious a charge naturally caused considerable sensation, especially amongst those who saw in it, as they see in every act of a Gas Committee, the possibility of another scandal. A meeting of the Committee seems to have been at once called; and the member who had been in some sense responsible for the statement offered an explanation, which is reported to have satisfied the Committee, and which he volunteered to make public in a letter to the newspapers. On being published, however, the letter proved to be, in effect, a reiteration of the original statement. Even those usually friendly to the Committee seem then to have thought there must really be something in it, and a demand was naturally made for a full explanation. This explanation is now forthcoming. It was made at the Council meeting last week, and is reported in another column. As might have been anticipated, it shows that great onterry was made about very little; and the Committee are neither the rogues nor the fools their detractors imagine. What really happened was that out of a considerable number of tenders three were selected as offering most nearly the kind of article the Committee required; and that in the long run, for reasons hereafter explained, one of the tenders at 9s. 3d. per ton was accepted, rather than one at 8s. 4d. per ton, or another whose price has not been publicly mentioned. As is well known, no canal is used at Rochdale. Gas of 18-candle power is manufactured from a mixture of two-thirds of high-

class coal, such as the Committee have now bought at 9s. 3d., and one-third nuts, which cost 7s. 6d.—the net price of the coal being, therefore, 8s. 8d. per ton. The coal at 8s. 4d. was thus apparently 4d. per ton cheaper than the material in use; but as it was found that it would yield only 17-candle gas, as against the 18-candle gas required, it was not bought. The other low-priced tender was also rejected after 100 tons of the material had been used in a working test; and the Committee practised the truest economy by buying the better, if apparently dearer, article. Another count in this tremendous indictment was that the Committee decided to send a deputation to the firm whose tender they accepted, with instructions "to do the best they could with them." The meaning of this apparently simple procedure was, of course, that an attempt should be made to get a modification of the terms of the tender, if possible; but it was sought to invest it in the public mind with some suspicion of jobbery or wrong-doing. The explanation of the Chairman of the Gas Committee, that the deputation succeeded in squeezing out of the contractors concessions to the value of £1000 in favour of the Corporation, should surely be sufficient to dispose of this latest and most flimsy of so-called "scandals." The case is, however, a fair sample of the kind of trouble which events have conspired to bring upon the heads of provincial Gas Managers and Committees. These gentlemen have to suffer for the sins of others, and so are deserving of much sympathy among their brother Managers.

THE HALIFAX GAS SCANDAL.

THE Halifax affair has developed very rapidly during the past week. At the Town Council meeting on Wednesday, the Mayor (Mr. Alderman Booth) signed the indemnity that was required by Mr. T. K. Fox, and made a very remarkable speech, the substance of which appears elsewhere. After the indemnity was signed, a sealed envelope, understood to contain Mr. Fox's allegations in set form, was opened; and a campaign of which we can scarcely yet see the beginning, to say nothing of the end, was thus begun. Mr. Fox's statement charged Mr. Alderman Riley, the Chairman of the Gas Committee, with "malpractices;" it accused Mr. Emor G. Wrigley, J.P., contractor for supplying coal to the Gas Committee, of fraud; and Mr. William Carr, the late Gas Manager, of corruption. It should scarcely be necessary to remark that the greatest caution is required in commenting upon these matters at this juncture, yet several newspapers have referred to them as though the whole case were proved by the Mayor's speech. There is some excuse for such rashness, in the reflection that any prudent man in the Mayor's position would have referred to the subject in more guarded language if the case had not been clear as daylight in his own mind. The responsibility for this strong speaking, however, rests with the Mayor. It is due to him that we should publish his observations, and treat them with all gravity. We are ready to admit, moreover, that the affair now looks different, as against the parties implicated, from what it did before this speech was made; but with this we must stop. It is reported that Mr. Wrigley has placed the matters personal to himself in the hands of his solicitors; and Mr. Alderman Riley has done the same. It is understood that Mr. Wrigley contemplates taking proceedings against the Mayor, while Mr. Alderman Riley's attention is directed to Mr. Fox. It is a question of commercial life and death with Mr. Wrigley; and Mr. Alderman Riley's personal and official reputation is at stake. Mr. Carr has not made any sign up to the present, save that his solicitors have again written to the local newspapers to beg for suspension of judgment. Meanwhile, it is announced that Mr. Carr's successor at the gas-works is to be chosen to-morrow. There is nothing more to be said upon the subject, now that the lawyers have been set to work.

GAS AFFAIRS IN SWANSEA.

THERE is a good deal of what diplomatists call "tension" in the relations between the Corporation of Swansea and the Gas Company, growing out of certain matters that were mentioned in these columns a few weeks ago. The worst of it is that as time goes on the bad feeling between the parties, who, for the good of all concerned, had better be friends, seems to intensify. It is not for us to assign the blame for this deplorable state of things; but if we had to do so, we should not heap it all upon one side. The Corporation opposed the Company in Parliament last session, as they had a right to do; and, as the Company allege, in consequence of this opposition and its results they are compelled to raise the price of gas. Always an unpopular step, this action of

the Company at the particular juncture has greatly incensed the Corporation, acting both in their capacity as the street-lighting authority and as representing the ratepayers and the gas consumers of the town. The Corporation inherit ancient statutory powers for establishing gas-works; and Counsel's opinion has been taken upon the question whether these powers remain in force, so that the Corporation could set up competing works. The case was laid before Mr. R. S. Wright, who has replied generally to the effect that the Corporation may set up gas-works if they like. Not content with this, the Corporation Committee who have had this matter in hand, have had a report prepared by the Town Clerk upon the question of electric lighting for the town, and have decided to recommend the Town Council to at once apply for a Provisional Order under the Electric Lighting Act. It will be seen from this meagre statement of the present aspect of gas affairs in Swansea that these might be upon a more comfortable footing. It is not to be supposed for a moment that there is any meaning in this flourishing of old statutes in the face of the Company; and there is a long way between applying for a Provisional Order for electric lighting and getting the lights to work. Not by these means can the Corporation inflict injury upon the Gas Company, if even they wish to do so. That the desire for reprisals exists, although it is to be hoped only for the time, seems tolerably clear. Local opinion accuses the Company of acting arbitrarily upon their powers, and "exhibiting feeling," which has culminated latterly in neglecting to invite the Mayor and Corporation to the luncheon which customarily follows the shareholders' meeting. Now to an outsider it would appear that when there is risk of a little misunderstanding between bodies situated like the Swansea Gas Company and the Corporation, mutual invitations to luncheon should be more frequent than usual, rather than the reverse. We do not suppose that the Corporation want the Company's luncheons; but if the Company have deliberately withheld the customary courtesy in consequence of any disagreement, all we can say is that they have not acted in a politic manner. If oil will not lubricate tight-running machinery, vinegar will never answer. We do not assign blame to anybody; but if the local newspapers are right in asserting that what is essentially a business difficulty is complicated and aggravated by displays of feeling on either side, then that side is in the wrong. We do not share the opinion of a local newspaper that the policy of reprisals between the Company and the Corporation is sure to benefit the ratepayers. It is rather the reverse. If the Corporation venture upon electric lighting, or any such retaliatory measure, they will repent it, and the ratepayers will suffer. The Company might then have reason for crowing over a discomfited adversary; but, between parties who have to live together, the less there is of triumphing over each other's blunders the better for both.

THE MANAGEMENT OF THE SALFORD CORPORATION GAS-WORKS.—Our readers will see, from the report which appears elsewhere, that, just on the eve of the recent strike of stokers at the Regent Road works of the Salford Corporation, Mr. J. F. Halligan resigned his appointment as Manager of that station. We understand that no successor to Mr. Halligan has yet been appointed, and that Mr. J. T. Sheard, F.C.S., who has had charge of the works all through the strike, is still superintending them.

THE ELECTRIC LIGHTING EXPERIMENT AT LEAMINGTON.—Our Leamington Correspondent, telegraphing last night, said: "The Leamington Town Council, at their meeting to-day, accepted an offer from Messrs. Chamberlain and Hookham, of Birmingham, to erect four arc lamps, five 300-candle incandescent lamps, and twenty-five 50-candle power lamps on the Parade, at a cost of £33, one-third of which the contractors will pay, and supply the electric current without extra charge. These changes are in consequence of the incandescent lamps of lower candle power having proved unsatisfactory."

OIL v. GAS FOR SMALL CONSUMERS.—We desire to call our readers' attention to the letter of Mr. J. S. Cranmer, Gas Engineer to the Stratford-upon-Avon Corporation, which appears in our "Correspondence" columns, in which he asks for information on the very important question of the competition of oil with gas among the smaller consumers. It is with this class that the paraffin lamp, with all its attendant dangers, is preferred to the gas-burner—possibly on the ground of initial cost solely; and it is in this direction that the efforts of gas managers are being put forth to extend the use of their illuminant. It will therefore be for the general good, as well as for the special benefit of our correspondent, if those of our readers who are in possession of information bearing upon the subject referred to in his letter, will respond to his invitation to communicate it to him through our columns.

Water and Sanitary Affairs.

AN increase of £2373 in the revenue of the East London Water-Works Company for the half year to Midsummer has been described in the Directors' report as "moderately satisfactory." At the shareholders' meeting last week, the Chairman (Mr. A. W. Gadesden) explained that this modest form of expression was due to the Secretary, who was desirous of seeing something more in the shape of an advance. Mr. Crooken-den may be supposed to look back to the three years immediately preceding 1884, when the annual increase ranged from £7000 to £11,000. A check was put on this growth, as intimated in the Chairman's speech, by the intervention of Mr. Archibald Dobbs and Mr. Torrens. In 1884 there was an actual decrease; but since that date the revenue has been rising, so that the former condition of things is nearly restored. But there was "a time before the flood"—not altogether to be forgotten—when the fortunes of the Company were especially low. Starting in 1807, the average dividend for the next fourteen years was only at the rate of $2\frac{1}{4}$ per cent. per annum. Prior to 1822, there were four years in which no dividend was paid. In those days very little was said about transferring the Metropolitan Water Supply to a public authority. Certainly the progress made has been remarkable. In 1809, the income of the East London Company was only a little over £10,000. Now the single half year brings in £127,000. In the ten years succeeding 1809, the gross revenue of the Company was trebled. It is also a notable fact that the average receipt per house is now somewhat less than it was in 1819; whereas the supply of water has been augmented. The varied character of the circumstances which affect a Water Company is shown by one of Mr. Gadesden's statements, in which he refers to the fact that the closing of two sugar refineries within the last twelve months has deprived the Company's revenue of between £4000 and £5000 per annum. The collapse of the sugar-refining industry in East London tells severely against the Company, owing to the reduced demand for water. But the domestic demand is good, and accounts for £2000 out of the £2300 by which the recent half year transcends the corresponding period in 1887. This source of income is happily free from violent fluctuations. The finances of the Company have been further assisted by the exercise of economy, and the occurrence of several favourable circumstances, in respect to the working expenses; the decrease of the current expenditure being almost equal to the increase of the revenue. Hence so good a surplus remains in hand, that one of the shareholders considers that the present dividend ought to have been $\frac{1}{2}$ per cent. higher. The desired dividend of $7\frac{1}{2}$ per cent. per annum is probably not far off; and a revival of the sugar industry would render material help in this direction. Among the existing difficulties of the Metropolitan Water Companies, we may mention the strange decisions occasionally given by the Magistrates in the Police Courts. The magisterial decrees often wear a very *ad captandum* aspect. The Chairman of the East London Company adverted to a case of this description, on which we recently offered some remarks. That houses should be left without proper cisterns to receive and store the water, is certainly a monstrous perversion of what is intended by the constant supply. If such an arrangement receives the sanction of the law, the consumer had far better revert to a supply on the intermittent system, with its accompanying reserve under his own control. Without this provision, the outbreak of a fire, or the execution of necessary repairs, may occasion serious inconvenience, by the sudden cessation of a supply otherwise constant, and relied upon as such.

LAST Thursday the Prince of Wales accompanied King Charles of Roumania to the ceremony of inaugurating the new works which have been constructed for supplying Bucharest with water.

WE have received from Bell's Asbestos Company, Limited, of Southwark Street, S.E., a copy of their new illustrated catalogue of asbestos manufactures. Although it is not ten years since the art of spinning this valuable mineral fibre by machinery was discovered by Mr. John Bell, the present Chairman of the Company, it is astonishing to find, from a glance at the pamphlet before us, how extensively its unique qualities of incombustibility and imperishability have caused it to be applied in the manufacture of materials used in various branches of engineering. There are several forms in which asbestos comes under the notice of our readers; for instance, in engine packings, paint, putty, and cement. But its many uses are fully explained and illustrated in the catalogue, which has been compiled with considerable care, and will be found serviceable in every engineer's office.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 651.)

THE event of the past week was the raising of the Bank of England rate of discount to 5 per cent., from the 4 per cent. rate which had lasted only three weeks. It is nearly two years since the rate was last raised to 5 per cent.—viz., on the 16th of December, 1886; and then it lasted until the 4th of February, 1887. The present advance, though not altogether unexpected, powerfully affected the Stock Exchange markets; and nearly all descriptions have suffered an abatement in price. Apart from this, there has been no disquieting influence in action either at home or abroad. The condition of the Gas market has been very similar to that of the week before. Slight modifications of quotation have taken place, and the reductions are confined to the stock of the Metropolitan Companies; while what little upward movement has been made is all in the Foreign category. Gaslight "A" furnishes the chief interest. It had closed weak, the week before; and it opened rather weaker on Monday. Not much business was done in it; but it fell $1\frac{1}{2}$. The next day it was rather worse; but from that point the decline was checked, and signs of rallying were evident, with brisk business. The drop was not recovered by the end of the week; but the stock had a rather better appearance at the close, though it is not quite clear what the next move may be. South Metropolitan have been almost dead; a solitary transaction in the "B" being all the business of the week. The flat tendency has extended to Commercial; and the old stock has fallen 3. The reason for this is not obvious, as the Company have been doing better business this year than for several years past. They had a highly gratifying general meeting on Friday; and everything was pleasant all round—a prosperous balance-sheet, a handsome dividend, and the welcome sight of the Chairman in his place again, looking as well as ever. Among the Foreign Companies, Imperial Continental continues to creep up, and marks a further rise of 1. Malta and Mediterranean has been unusually brisk; and a scent of better things to come is palpable in the air. Other undertakings offer nothing whatever of interest. There is more activity in Water; and, for the first time for a considerable period past, there is a drop in the quotations, though very slight.

The daily operations were: Restricted business in Gas on Monday. Gaslight "A" was weak, and fell $1\frac{1}{2}$; but Imperial Continental was 1 higher. Metropolitan of Melbourne was fractionally better on *ex div.* quotation. Water quiet and unchanged. On Tuesday, Gas was quiet again, without variation. Water was active, and several issues changed hands at excellent figures. On Wednesday, there was considerable dealing in Gaslight "A," with a better tendency; but the quotation did not move. Commercial old was marked at 271—falling 3. Water was less active; and prices were about the average. There was increased activity in Gaslight "A" on Thursday, at about the same prices as the day before. Imperial Continental was firm and active. Very little business in Water, and prices showed a marked tendency to droop. Friday's business in Gas was much the same as the day before—all issues dealt in being steady. Business in Water was all in Southwark, and at moderate figures. New River fell $1\frac{1}{2}$, and Lambeths fell 1 each. On Saturday, Gas was quiet; but prices for the most part were good. Water was not dealt in.

ELECTRIC LIGHTING MEMORANDA.

THE AFFAIRS OF THE MAXIM-WESTON COMPANY—THE LESSON OF BARNET—THE APPLICATION OF ELECTRICITY TO MINERS' SAFETY-LAMPS—MR. H. E. JONES UPON ELECTRIC LIGHTING AND GAS IN AMERICA.

THE sensation of the week in business circles interested in electric lighting was the publication of the recent history of the Maxim-Weston Company. An extraordinary general meeting of the shareholders was held on Wednesday—the new Chairman (Mr. John Marks) presiding—to consider a resolution for reducing the capital of the Company from £125,000 in shares of 5s. each, to £62,500 in shares of 2s. 6d. each, by cancelling lost capital. In moving the resolution, the Chairman made a general statement referring to the condition of the concern, and reflecting in strong terms upon the conduct of the late Chairman, Mr. Hugh Watt, M.P. It is notorious that the present Board were appointed in opposition to Mr. Watt; and he seems, in consequence, to have made himself as disagreeable as he could. The new Directors were for some time unable to procure access to the Company's books; and the Secretary, who was one of Mr. Watt's own clerks, refused to carry out their instructions. A deadlock of some months' duration ensued, which was terminated by the resignation of the old Chairman and the dismissal of the Secretary. As soon as the new Directors obtained possession of the books and other property of the Company, they had a valuation made, with the result that the picture of the Company's state as presented by Mr. Watt was found to be altogether illusory. The cancellation of capital in question on Wednesday was the first step considered necessary by the Directors to put the affairs of the Company upon a proper basis. Although the shareholders must have been bitterly disappointed at the condition of the concern as revealed by the Board, they fell into the proposed arrangement; and the lost capital was accordingly written off. The next thing they will have to do, if the Company is to be saved, is to find £23,500 for working capital. Meanwhile Mr. Watt has issued a circular stating his own view of the circumstances attending his retirement from the control of the Company's affairs, and has presented a petition to the Court for the winding-up of the Company,

which will come before the Vacation Judge to-morrow. In all probability there will be some more "washing of dirty linen in public" before the Maxim-Weston undertaking is extricated from its present straits.

It was mentioned in the JOURNAL last week (p. 603) that the enterprising town of Barnet had had another experience of the shady side of electric lighting; the whole of the street lamps having gone out one foggy evening and remained unlit for hours, owing, as it was stated, to a breakdown of the steam-engine. We observe that the newspapers that were loudest in applauding the little suburban town for its "public spirit in adopting the light of the future, while London lagged hopelessly behind," &c., make no mention of these little inconveniences. They must not be overlooked, however, by the best friends of electric lighting. We are not so ignorant of what can be done with electric lighting machinery, as to argue that because the Barnet lamps occasionally go out and leave the streets in darkness, therefore no better can be done elsewhere. The temptation to exhibit the black side of the Barnet experiment is hard to resist, seeing how ridiculously it has been vaunted in some newspapers, the conductors of which should have known better. In reality, however, we refer to these troubles chiefly to show that the electric lighting of a town, in order to be satisfactory, must be deliberately entered upon, and conducted upon a properly worked-out plan. It is all very well for a local board who have fallen out with the local gas company to send for a contractor for electric lighting, and after parleying with him for a week or two, to entrust him with the lighting of the streets by means of a "scratch" installation. That sort of thing is very smart, as some people understand smartness, but it has the disadvantage of not standing wear and tear. The true lesson of Barnet is only the lesson of half-a-hundred other towns in the kingdom that have dabbled in electric lighting to their loss and disappointment. If good electric lighting is wanted anywhere, the plant must be properly laid down. Bradford, for example, is going the right way to work to get a satisfactory result; and if disappointment should be experienced there also, it will not be due to haste and want of sufficient consideration on the part of the designers of the lighting plant.

There was an exhibition of miners' electrical safety-lamps in the Mechanical Science Section of the British Association meeting this year, to illustrate a paper presented by Mr. Nicholas Watts. Among others were shown and described the Swan lamp, which is maintained by a four-cell secondary battery grouped together in a block of gutta-percha, which is enclosed in a wooden case. The luminosity is from 1 to $1\frac{1}{2}$ candles for ten hours; and the lamp weighs 7 lbs. It is said to be in extensive use in South Wales. Then the Schanschieff lamp was shown; this being maintained by a single liquid primary battery. The luminosity is (with reflector) 2 to 3 candles for nine hours. Other lamps named were the Pitkin, the Portable Electric Syndicate, and the Vaughton, with secondary batteries, and the Walker with a simple primary battery. All these lamps cost from 21s. to 30s. each, and the working expenses average about 1d. per lamp per day. Mr. Watts seemed to think well of the prospects of lamps of this order for coal miners' use; but did not settle the question whether primary or secondary batteries are to be preferred. Also he did not think the position of the lamp on the stand was finally settled.

The interesting question of the position of electric and gas lighting in the United States has been discussed by many authorities; but the latest, and not by any means the least valuable, is the brief statement volunteered by Mr. H. E. Jones, the Engineer of the Commercial Gas Company, at the meeting of the proprietors last Friday, a report of which will be found in another column. Mr. Jones went about with his eyes open; and he had the advantage of being able to complete his own observations by information obtained from gas engineers in all parts of the great continent, who were able to supplement his passing opinions by permanent records. There can be no doubt that Mr. Jones is a witness of truth when he says he saw everywhere in the States electric lighting and gas and oil in full use side by side. This report rounds off what peripatetic electricians say of the electric light in America. They have habituated us to hear of the popularity of the electric lamps in American towns, small and great; but they have omitted to say that fashionable electric lighting is contemporaneous with a lively business in gas and oil. That is what Mr. Jones tells us; and the message is worth carrying across the Atlantic. The utmost that our British electricians seem to hope for is that they may in time realize the good fortune of their American compeers. If this aspiration is to be granted, it is to be hoped that British gas companies may likewise emulate the growth of the American undertakings referred to by Mr. Jones as increasing their gas production at the rate of 20 per cent. per annum. It is rather to be regretted that Mr. Jones did not return in time to give his view of the matters dealt with by Professor Forbes before the recent British Association meeting. Possibly, however, Mr. Jones may be induced to say a little more upon the subject than he could find time for last Friday.

THE next ordinary general meeting of the Institution of Mechanical Engineers will be held on the 24th and 25th inst., at 25, Great George Street, Westminster. The business to be transacted includes the election of new members and associates, and the nomination of officers for election at the next annual meeting. Discussion will be resumed on two papers read at the last meeting; and two new papers will be read and discussed—one on "The Rathmines and Rathgar Township Water-Works," by Mr. A. W. N. Tyrrell.

THE PRESERVATION OF GASHOLDERS FROM RUST.

THE attention of gas engineers has been much drawn by recent discussions to the fact that gasholders are unstable structures. They are also perishable erections, which is a further consideration that engineers cannot afford to lose sight of. Sooner or later the best constructed holder requires re-sheeting; and long before it arrives at this extremity, it has demanded periodical attention and occasional patching. Time was when this tendency to decay was almost wholly confined to the holder itself; the guide-framing, being mostly of cast iron, was to all intents and purposes everlasting. Since guide-framing has been made chiefly of wrought iron and steel, however, this condition has changed; and the care of the engineer for the preservation of his work has extended to the fixed as well as to its moving portions. The fact has been generally recognized, although the understood tendency of wrought iron and steel to rust, unless thoroughly protected by painting or otherwise, has not been allowed to stand in the way of their employment in these structures. The utmost regard that has been paid to this consideration is in respect of discouraging forms of construction which would prevent periodical painting. It has been a particular rule with designers of gasholders for which wrought iron or steel-guide framing has been chosen, that the pieces of the latter should never be so disposed that a paint brush could not be applied to every part. Notwithstanding all this care, however, the protection of the material of gasholders from rust is a serious trouble; and holders often cost large sums annually for scraping and painting, which nevertheless does not long preserve them from decay. At a time when the subject of gasholder construction is attracting general notice, it may be well to devote a little space to the discussion of this part of the question, which must always be important whether external guide-framing is modified or abolished; for if the columns and stays are done away with, the sheeting will remain, and this is the most perishable part of the work.

Gasholders wear out or decay sooner or later, as everybody knows; but it is not always easy to state the real causes of the observed effects. Old holders last a very long time in some places and under certain conditions; and, in fact, commonly fall to be removed rather because their room is required for the provision of larger storage than because of their own unfitness for work. On the other hand, quite new and apparently well-made holders may require extensive repairs and re-sheeting, although worked under precisely similar conditions. Some holders are racked almost in pieces by strains acting on the side and top sheeting, as is shown by distortions of their shape and incurable leaking. This may be due to bad design in the first place, the material being wrongly disposed; or, of course, leaking may be simply owing to bad workmanship in the erection and rivetting. In some cases, however—and it is these we especially desire to discuss—the sheeting and guide-framing (particularly the former) rust out under the engineer's eyes; the progress of decay commencing with local blistering and pitting, and ending only with the ruin of the whole structure. What are the causes and cure of this deplorable decay?

In the first place, regard must be had to the quality of the materials used. Most engineers can recall instances of old holders that have never had much attention except an occasional tarring outside—the latter sometimes repeated until the semi-plastic coating hangs upon the iron in dirty creases, looking like the hide of a rhinoceros—and are yet, so far as the metal is concerned, in perfect preservation. Against these may be set the examples of new holders decaying as already mentioned. Here the quality of the iron becomes the first subject of inquiry. In all probability the iron in the old holders was of the finest brand procurable at the time, and cost perhaps £25 and upwards per ton before any work was done to it. It is unnecessary to ask what the new iron may have cost. The old holder was made of sheets as fine in texture as copper, and as ductile and free from cinder. The modern article may be as scaly as a piece of slate; so that it contains all the elements necessary for rapidly disintegrating as soon as the skin is pierced and oxygen can get at the interior. We do not hesitate to declare that many modern holders are made of sheets of rubbish that can only be called iron by misplaced courtesy. Even when care is taken to specify a material possessing a certain tensile strength, and the requirement is insisted upon, the iron that satisfies the mechanical test may be utterly unfit for use in a structure intended to possess endurance rather than strength. A hard dirty iron, coarsely laminated, may withstand a considerable pull along the grain when new; yet it will rot like paper as soon as the skin is broken and it is exposed to alternations of wet and dry in a sulphurous atmosphere. Competition in price is, of course, the origin of the practice of putting iron of this character upon the market. It is idle to blame the gasholder builder for all of the failing. He must cut down his tender in order to obtain work; and he is compelled to buy the cheapest material that will satisfy the specification. It is no concern of his how long the structure will last after he has received his last payment on the contract.

In point of fact, the treatment which the sheets of iron composing a gasholder receive is very severe. They are flattened and punched, and the seams are sometimes heavily strained in course of the rivetting; then the metal is painted or tarred, and immersed in dirty water, from which it rises to be dried in air, or, as it may be, to be drenched by rain, day after day and year after year. It is expanded by heat or shrunk by cold. If the paint dries hard, it cracks when the iron expands; and the water attacks the iron beneath. It is no wonder that under such treatment the poor

laminated iron which the gasholder builder is driven to buy gives way, and blisters and gets into holes under its coverings. If gasholder sheeting is wanted to last any length of time, therefore, the first thing to insist upon is that the metal shall be of good quality—not merely strong in the mechanical sense, but pure also. There is no difficulty about this. Good iron is made now, as it always has been; and although there is no necessity for making gasholders of charcoal sheets, a reasonable degree of purity will always favour the life of the material when exposed to deteriorating influences. Gasholder sheets require to be fairly hard, to preserve rigidity of form; but the hardness need not mean scaliness. It is customary for the sheets to be specified to be oiled or painted at the maker's works before delivery. Anyone who has walked through a gasholder yard, and noticed the sort of stuff that is frequently so treated, may well entertain doubts respecting the utility of the process. Dirt and rust are not always carefully removed before the imaginary preservative is applied; whereas, to be effectual, this process requires even the removal of the scale. What is wanted, therefore, is a pickling process in weak acid, and subsequent brushing, before the plates and bars are oiled or coated. Without this it is better to let the iron rust, and throw off the scale, if it will, before attempting to paint it. Half the mischief with iron is traceable to this one cause—scale. Even after having become pitted with rust, iron may be saved by drying and painting; but not if corrosion goes on untouched under a delusive hard coating of scale. Steel should always be cleaned from scale before painting; for, as it is much more easily corroded than iron, it needs more careful treatment from the first.

Supposing, now, that a gasholder has been well made, of good and tough materials, properly cleaned at the works, and coated with a skin of boiled oil before being dispatched for erection, what is the best thing to do with it after the erection is finished? We are not going to advertise anybody's paint or process. As for paint, practical men who have used much pigment upon ironwork know pretty well what to expect from it, and are not over-much impressed with all that is advanced by different makers in recommendation of their wares. A good deal has been published of late respecting the advantages of soapstone as the solid basis of paints intended for the preservation of ironwork; but experience of this compound with gasholders is wanting. The great desideratum with ironwork paints is that, while they should dry thoroughly in a comparatively quick time, seeing that many holders must be painted while in use, they should not dry so much as to lose their nature, or become scaly or powdery with time. There is the main difficulty. Notwithstanding all that is advanced on behalf of the claims of some paints to special "anti-corrosive" qualities, we hold to the opinion that the value of a paint is a question entirely of its tenacity, adhesiveness, and the preservation of its body after drying. The "anti-corrosive" influence of the solid part of the constituents of a paint upon the material which it covers must be chiefly imaginary. If the paint will only *preserve itself*, and stick to the iron, it does all that paint can do. No matter what may be the chemical composition of a paint, the obligation to scrape it off if it blisters and leaves the iron is imperative; and the same may be said if it shows a tendency to crumble to powder. Hence it may be deduced that what French engineers call the "agglomerant" is after all the mainstay of any paint.

The cost and temporary character of painting for preserving ironwork have induced some engineers to fall back upon coal tar as a preservative for their gasholders. The most artificial preparation of tar for this purpose is the well-known "black varnish;" and excellent stuff it is, when properly made and well laid on. It is all that can be desired for the inside of holders; its powers of adhesion and preservation being perfect. Unfortunately, it shares with other preparations of tar the unpleasant tendency to turn a dirty sage-green when exposed to the air. A remarkable instance of this once came under the writer's notice. The cast-iron columns of a large new holder had just been finished with a coat of the varnish when there came a heavy thunderstorm, which burst right over the works with frequent lightning and sheets of rain, lasting perhaps an hour. When the rain ceased, the glossy black columns were seen to be all turned this dirty light sage-green tint, which lay like a skin on the surface of the varnish; and the appearance of the work was spoiled. Tar simply boiled to expel the water, hardened by the addition of a little lime, and made drying with naphtha, is commonly used for gasholders, and is very good for its kind. It leaves a holder black, however, which is not an advantage for the summer; and so the surface is sometimes lightened by a wash of Portland cement mixed very thin with water and simply laid on with a whitewash brush. The different capacities of the iron, tar, and cement for expansion with heat are apt to cause cracks, however, which require attention. Still, the preparation is a very useful one.

The subject of the preservation of gasholders from corrosion is, however, a matter that can only be fairly treated by the examination of recorded experiments and observations, and investigation of details, which cannot be compressed into the space of an article. Many engineers possess data referring to the covering power and durability of paints and varnishes, upon which their practice in this regard is based. It would be interesting if some of this information could be collected, and made generally available by means of a communication to one of the technical societies.

At the first meeting of the Council of the Sanitary Institute last Friday, at the Parkes Museum, Sir Douglas Galton, K.C.B., F.R.S., was unanimously appointed Chairman.

FINDING WATER AND METALS BY DIVINATION.

THE remarkable experiments in the art of rhabdomancy, to which reference was made in a recent number of the JOURNAL, justify some further examination. If modern times furnished but a single example of this mysterious power, it would scarcely be worth while to turn to past records for additional illustrations. But investigation is excused, if not demanded, when we find that in the course of a few months rhabdomancy has been successfully practised by different adepts in widely-separated parts of the kingdom. In the previous article on this subject we quoted what had occurred (1) in Suffolk, (2) in Sussex, and (3) in the North of Ireland.* And, moreover, the London newspapers have quoted the names of a number of noblemen and gentlemen on whose estates it is said Mr. Mullins has been no less successful than in his experiments at Hastings. Thus there are at the present time at least three men in England who claim to be possessed of a power which, viewed from an ordinary standpoint, and by the light of everyday experience, must be regarded as inexplicable. But facts are always stubborn things; and facts must be admitted by those who have witnessed the extraordinary performances in question, even though they are unable to put forward any acceptable explanation of what has been demonstrated in the face of a "cloud of witnesses." Having had these modern instances forced on our notice, let us glance at what has happened in the past.

But, first of all, the question arises, what is the meaning of the term "Rhabdomancy"? The answer is that we are to understand by the use of this word the power—partly natural and partly acquired—claimed by some individuals of discovering things concealed beneath the surface of the earth, more particularly metals and running waters. This art is said to be exercised through the agency of certain instruments, of which the best known is the divining-rod. There are, beside, the sidereal pendulum and the bi-polar cylinder; but of these latter we do not now propose to speak. According to an Italian work, which was translated into German in the early part of the present century, persons who possess the peculiar gift under discussion are liable, when in the vicinity of subterranean channels of waters or of bodies of ore, to a marked alteration of the pulse, a rapid change in temperature, and sometimes to convulsive symptoms which are scarcely distinguishable from those produced by ordinary electric shocks. From the most remote period, remarks a German writer, indications are found of an art of discovering veins of ore and water concealed in the bowels of the earth by direct perception of their existence unaided by ocular demonstration. In France and in Switzerland resort to this art has been far more common than in our own country, and has been subdivided into metalloscope, or the art of discovering metals, and hydroscope, or the art of discovering water. It was in the middle ages that the practice of rhabdomancy attained the most remarkable development; but, although many of the feats which were then recorded may be held to have been accomplished in a fraudulent manner, there are other examples which it is impossible to put aside as entirely undeserving of credence. Mr. Baring-Gould, in whose interesting work on "Curious Myths of the Middle Ages," many of the Jesuit and other works on this subject are carefully cited, quotes at some length the experiments made by one Bleton, whose powers as a detector of unseen watercourses attracted the widest possible attention. A number of medical men set themselves to subject this expert to a series of tests, which, in their judgment, precluded the possibility of fraud. Bleton, although sometimes using a hazel-branch, did not consider it indispensable to the success of his experiments. He was content to employ a stick picked up from the road, provided it had not come from an elder tree. It was not requisite that the rod should be fork-shaped. If the rod used were straight, it was customary for it, when held by the operator, to rise slightly at the extremities, but not to turn. If bent, it revolved on its axis with more or less rapidity, in accordance with the volume of the detected water and the force of its current. A further phenomenon in regard to this man's performance was that he was able to make the rod turn between another person's fingers, even without touching or seeing it, by merely approaching or leaning his body in the direction of the stick, provided he was at the time standing over a subterranean watercourse. But if the operator were insulated on glass, silk, or wax, his sensations were less vivid, and the stick ceased to rotate. It appears to be certain, however, that in some instances Bleton's powers absolutely failed him. Concerning another human hydroscope, who was born near Marseilles in the year 1760, Mr. Baring-Gould mentions some singular circumstances. He was said to experience sensations of horror when near water, the existence of which other persons had not the slightest reason to suspect. Vincent Amoretti, an Italian, also was reported to undergo peculiar sensations when brought into proximity to water, coal, and salt, and was skilful in the use of the divining-rod. But, to come nearer home, reference is made to Vol. XXII. of the *Quarterly Review*, in which the astonishing performances of an English lady are circumstantially set forth. This lady, it is said, indicated to a Dr. Hutton the existence of a spring of water in one of his fields adjoining Woolwich College, which, in consequence of this discovery, he was enabled to sell to the College at an enhanced price. The lady in question exhibited her powers not once but on many occasions, and in the presence of witnesses whose statements the

* A correspondent has written to the *Morning Post* mentioning the names of two young men at Abergele who are said to be very successful in "divining" both for water and minerals.

Quarterly Reviewer of that day (1820) held it to be impossible to disbelieve.

Many somewhat similar instances might be cited from the pages of certain other writers, but for the need of confining our remarks within certain limits. Enough, however, has been said to show that there is a far-stretching and continuous chain of evidence which tends to prove that in all ages rhabdomancy has had its representatives. The claim to exercise this mysterious power is no new thing. Precedents are abundant. It would then be well if, once for all, the doubts and difficulties surrounding the question could be set at rest by systematic and practical tests, to which there is reason to believe every one of the three rhabdomatists whose names have been mentioned in connection with recent experiments would be perfectly willing to submit. One of them in particular—Mr. John Stears, of Hull, whose remarkable feats at Lisburn we described in our previous article—has, in his letter to a contemporary from which we quoted last week, challenged anyone and everyone who may be disposed to investigate the phenomena of which he is so successful an exponent. This challenge ought not to be disregarded. Mr. Stears plainly says that he possesses the power of finding both metals and water, when, to ordinary humanity, they are out of sight and imperceptible. Is this true, or is it false? If the former, the fact should be placed beyond all doubt. If it is false, the deception ought to be established; and the sooner the better. Mr. Stears claims to have used the divining-rod successfully for a period of nineteen years. Certainly, no one has come forward to dispute the accuracy of his representations; while, on the other hand, there are plenty of persons who would feel constrained to bear witness to what was accomplished by him at Lisburn, as set forth in these columns. One circumstance which Mr. Stears mentions in his letter deserves to be borne in mind in connection with the tests formerly applied to Bleton—viz., that if the rhabdomantist stands upon two china dishes all his power is lost. Mr. Stears views this as a conclusive indication that the gift he possesses is attributable to electricity. Herein may be the key to the whole matter, or at least a clue, which, in so highly cultivated an age as ours, should help to guide to a true and rational conclusion, those who set themselves to probe the subject. The impartial observer, though naturally averse to admit the existence of magnetic forces which he does not understand, will nevertheless pause before he scorns all theories and explanations which are not to be summed up in the one word "fraud." The history of scientific progress should at least teach us to approach such questions with open mind. Mesmer, in his day, was jeered at, and his professions scornfully pooched. But the man who would now-a-days deny the existence of mesmeric force would be set down as an ignoramus. Mesmer adopted the part of a charlatan, and perhaps deserved to be discredited. In like manner some of the professors of rhabdomancy may have played tricks in their day and generation; and yet it is conceivable that rhabdomancy is not, from beginning to end, a false pretence or a delusion. We hold that, in the interests of truth, the subject deserves thorough investigation.

Communicated Articles.

THE GUIDE-FRAMING OF GASHOLDERS.

FOURTH ARTICLE (continued).

We will now apply the rules for the strength of guide-framing to a few actual examples, commencing with gasholders of the

CANTILEVER TYPE.*

Example I.—South Metropolitan Gasholder, Old Kent Road. Designed by Mr. George Livesey (I shape, web-plate Standard, see Fig. 37 c.)

D (the diameter of gasholder)	= 214 feet.
H or d. (the total height of holder)	= 160 "
N (the number of standards)	= 24 "
B (the distance centre to centre of standards)	= 28½ "
A (the effective sectional area of back flange)	= 10 sq. inches.

Now applying formula for bending moment, due to distorting influences,

$$\frac{B \cdot H \cdot A}{270} = \frac{28\frac{1}{2} \times 160 \times 160}{270} = 2702 \text{ (inch-tons).}$$

The standard being in effect a plate girder, and the front flange having so much more material in it than the back flange, the neutral axis will not pass midway between the flanges, but through the centre of gravity of the cross section of the standard. Therefore in determining the moment of resistance of the standard, we must take the sectional area of either flange, and multiply it by its distance from the neutral axis. Twice the product into the resistance of the material (per square inch) will give the moment of resistance (R) very nearly.†

In this particular example the centre of gravity of the cross section of the standard is easily determined to be 19·3 inches from the back flange. The effective sectional area of the back flange is about 10 square inches. This multiplied by twice the distance from the neutral axis = $10 \times 19\frac{1}{2} \times 2 = 386$. The bending moment we found to be 2702; which, divided by the above, will give the actual strain upon the iron per square inch, or 7 tons per square inch, due

to distorting strains set up in the holder by the one-sided application of the wind pressure, and through it communicated to the standards.

Now, applying the rule for *dead thrust*, we have

$$\frac{24d^2 + D^3}{5040 N} = \frac{(24 \times 160 \times 160) + (214 \times 214)}{5040 \times 24}$$

= 5½ square inches required. The spare section about the neutral axis of the web plate in the standard is competent to meet this dead thrust; the total section of web being equal to 10 square inches fully.

Strain on Ties and Struts.—Referring to the third article, we find S_1 , the vertical shear =

$$\frac{24d^2 + D^3}{10,000} = \frac{24 \times 160 \times 160 + 214 \times 214}{10,000} = 66 \text{ tons.}$$

which, resolved in the direction of tie = $66 \times 2\cdot05 = 135$ tons.

" " " " strut = $66 \times 1\cdot75 = 115$ tons.

There are five bays of double bracing =

$$1 + 2 + 3 + 4 + 5 = 15.$$

Strain in— Effective Section allowed.

First or top set	= $\frac{1}{15} \times 135 = 9$ tons	2 bars	$4 \times \frac{1}{4} = 4$ sq. ins.
Second "	= $\frac{2}{15} \times 135 = 18$ "	"	$5 \times \frac{1}{4} = 5$ "
Third "	= $\frac{3}{15} \times 135 = 27$ "	"	$6 \times \frac{1}{4} = 6$ "
Fourth "	= $\frac{4}{15} \times 135 = 36$ "	"	$7 \times \frac{1}{4} = 7$ "
Fifth or bottom	= $\frac{5}{15} \times 135 = 45$ "	"	$8 \times \frac{1}{4} = 8$ "

The strain per square inch is, therefore, 2½ tons on the top set; and increasing to fully 5½ tons per square inch on the lowermost set, which is quite safe.

Strains on the struts:—

First or top ring	= $\frac{1}{5} \times 115 =$ (say) 8 tons.
Second "	= $\frac{2}{5} \times 115 =$ " 16 "
Third "	= $\frac{3}{5} \times 115 =$ " 23 "
Fourth "	= $\frac{4}{5} \times 115 =$ " 30 "
Fifth "	= $\frac{5}{5} \times 115 =$ " 38 "

The effective sectional area of each strut is something like 15 square inches; so that in the lowermost one, it is only about 2½ tons compression per square inch, whereas in the top ring it is only about ½ a ton. (See Note P.)

Example II.—Large Gasholder at Birmingham. Designed by Mr. Charles Hunt.

D = 233 feet. d or H = 150 feet. N = 26. B = 29 ft.

K = 60 ins. A = 16 square inches (effective).

Applying the formula $\frac{B H^2}{180 K}$ we have $\frac{29 \times 150 \times 150}{180 \times 60} = 60\frac{1}{2}$ tons.

Allowing a strain on the iron of 5 tons per square inch, we require say 12 square inches in each flange. The actual effective area is 16; so that we have a margin of 4 square inches in each, or a total of 8 square inches to meet the thrust and lift strains. These

by the formula, $\frac{24 d^2 + D^3}{5040 N} = \frac{24 \times 150 \times 150 + 233 \times 233}{5040 \times 26}$

= 4½ square inches required. One boom only is therefore sufficient to meet these strains. The ties in this case attach to the back flange or boom of the standard; so that the strains they induce are chiefly carried or transmitted by that flange.

As regards the bracing between the standards, the number of panels or sets of struts and ties are the same as in the last example—viz., five—and on applying the formulæ, it will be found that the strains are almost precisely the same, bar for bar, as for the previous example; but the sections of iron allowed are a little stronger. We need not repeat the method, as it would practically agree with the above.

In both these examples, we note that the ties and strut in the upper part appear much stronger than needful to meet the estimated strains; but this is correct for the following reasons:—

(1.) The excess of strength in the upper struts, together with the wind ties (sometimes called Paddon's ties), help to resist the tendency of the framing to distort out of shape horizontally, as they act like so many stiff rings or curbs. This help is most needed at the top, because the lower portion of the cylinder of the guide-framing is fixed to the solid tank, and cannot therefore distort out of the circle; but the upper part depends upon the stiff rings not only in the holder, but in the framing itself, quite as much as upon the stiffness of the standards acting as independent posts or cantilevers.

(2.) The wind pressure and other overturning forces act upon the standards through the roller carriages, which, of course, are at points up the standard; and therefore, properly speaking, the forces are not uniformly distributed. A great deal of the force is given out by the top rollers at the top of the framing, making the upper part of the standard like a beam loaded at one end only; and therefore increasing the strain on the top bays. These are good reasons for the apparent excess of strength.

NOTE.—It is, of course, an easy matter to determine the strains due to the forces acting at points up the front of the standards, instead of being distributed as we have taken them; but for all practical purposes, we may take as a reliable rule that the top ties should not be less than half the sectional area of the bottom set—the others being proportionally treated. The struts should be of equal strength and stiffness throughout, so as to resist distortion.

Example III.

The largest gasholder in the world is the four-lift one erected at the East Greenwich works from the designs of Mr. George Livesey. The guide-framing is carried to the full height of the gasholder, and consists of 28 wrought-iron web-plate standards of

* See Third Article (Vol. LI., p. 189) for method of treatment.

† This is not strictly correct; but it is very near the truth.

I section (see fig. 37D), braced together into one huge cylinder by six tiers of struts and systems of diagonal bracing.

D (the diameter of gasholder) = (say) 250 feet.

H or d (the total effective depth) = — 180 „

N (number of standards) = — 28 „

B (centre to centre of standard) = (say) 28 „

Assuming that the top curb is able to offer resistance to distortion at the top, aided by the Padden's ties, we have—

$$M = \frac{BH^2}{270} = \frac{28 \times 180 \times 180}{270} = 3360 \text{ inch tons} = \text{the bending moment on each standard.}$$

The cross section of the standard displays a great deal more material in the front than in the back flange; and, being a web-plate girder, the neutral axis will fall nearer to the front flange, or about 20 inches from the back flange. The sectional area of the back flange is fully 11 square inches effective. $11 \times 20 \times 2 = 440$.

$$\frac{M}{440} = \frac{3360}{440} = 7.6 \text{ tons per square inch.}$$

This is the strain on the flanges of the standard, due to the *distorting* influence of the maximum wind pressure on the whole gasholder.

The dead thrust on one standard, due to the overturning action of the wind, requires by the formula—

$$\frac{(24 \times 180 \times 180) + (250 \times 250)}{5040 \times 28} = \text{nearly 6 square inches.}$$

The sectional area of the web is 9 square inches. The metal about the neutral axis, together with the concrete filling in the front guide, will therefore fully meet this strain of dead thrust on the standard, due to the *overturning* action of the wind.

We still have the bracing to treat of. Applying the formula for vertical shear—

$$S_1 = \frac{24d^2 + D^2}{10,000} = \frac{(24 \times 180 \times 180) + (250 \times 250)}{10,000} = 84 \text{ tons.}$$

The bracing between the standards consists of six tiers of horizontal struts and two distinct series of cross ties; one set being of steel (represented in fig. 39 by the thick lines), and the other of wrought iron (indicated in the illustration by thin lines).

We will deal with each series separately, and as resisting the whole vertical shear (84 tons). Taking the main steel ties first, the 84 tons resolved in the direction of these main ties = 116 tons. As there are six panels of ties in the height, we have :

$$1 + 2 + 3 + 4 + 5 + 6 = 21.$$

Strain in—	Square Inches.
Top tier = $\frac{1}{6}$ of 116 = 5.5 tons.	2
Second „ = $\frac{2}{6}$ of 116 = 11.0 „	3
Third „ = $\frac{3}{6}$ of 116 = 16.6 „	3½
Fourth „ = $\frac{4}{6}$ of 116 = 22.2 „	4
Fifth „ = $\frac{5}{6}$ of 116 = 27.6 „	4½
Bottom „ = $\frac{6}{6}$ of 116 = 33.2 „	5

The lowermost ties are 10 in. by $\frac{5}{8}$ inch. The effective sectional area, after allowing for the riveted junction, equals (say) 5 square inches, which is therefore less than 7 tons per square inch—a very safe working strain for steel. The ties decrease an inch in width every bay; the topmost being 5 in. by $\frac{5}{8}$ in. There is therefore but little more than 2 tons per square inch on the top ties; the balance of strength going towards preservation of form, &c., as already explained.

We see from the above that, providing the standards are stiff enough in themselves, the main steel ties are all that would be

required; but in this case they would lack lateral stiffness, unless braced intermediately—the pitch of the main steel ties being about 30 feet; and we must remember that the formula applied to the standards assumes that they (the standards) are thoroughly lashed together into one complete cylinder.

We will now consider the whole shear (84 tons) as coming upon the secondary ties only. Resolving it into the required direction, we have 156 tons, and halving it, because there are two pairs of ties in each panel, we get 78 tons as the inclined pull, to be split up amongst the six panels, or strain on

Top tiers = $\frac{1}{6} \times 78 = 3.7$ sectional area allowed = $2\frac{1}{2}$ sq. ins.
Second „ = $\frac{2}{6} \times 78 = 7.4$ „ „ = 3 „ „
Third „ = $\frac{3}{6} \times 78 = 11.1$ „ „ = 3½ „ „
Fourth „ = $\frac{4}{6} \times 78 = 14.9$ „ „ = 4 „ „
Fifth „ = $\frac{5}{6} \times 78 = 18.5$ „ „ = 4½ „ „
Sixth „ = $\frac{6}{6} \times 78 = 22.2$ „ „ = 5 „ „

The strain on the most severely strained tie is thus barely $4\frac{1}{2}$ tons per square inch—a very safe strain for wrought iron in tension.

We see, therefore, that we have two distinct series of ties, each capable of standing the entire strain. No doubt the object has been, not only to give the standards greater support laterally, but likewise to provide against the possibility of a tie snapping; because if one tie snaps, it might upset the whole structure—like the snapping of one link in a chain. In the cantilever form of construction, so much depends upon the ties being taut, and not giving way, unless the parts are duplicated as in this instance.

As regards the struts, by applying the process already described, we find the strain on the bottom one = 22 tons compression. The section of the strut is ample and well adapted by its form to resist this thrust; so we need not enter further into details.

The foregoing are examples of holders having the guide-framing carried to the full height, and with wrought-iron framed standards. The next example will be one where the guide-framing stops at the middle lift, and having cast-iron columns braced into one cylinder.

Example IV.—Rotherhithe Gasholder.

D = 153. d. or H = 75. N = 18. B = 30. d_1 (diameter of column) = 36 inches. Thickness (say) 1 inch. Two tiers of girders to act as struts, with strong flat-iron ties between.

Applying the formula, we find that the sectional area of one column required to meet the distorting strains only equals—

$$\frac{1.6 B H^2}{130 d_1} = \frac{1.6 \times 30 \times 75 \times 75}{130 \times 36} = 58 \text{ square inches.}$$

Sectional area required to meet direct thrust and lift-strains for one column=

$$\frac{24 d^2 + D^2}{3360 \times N} = \frac{24 \times 75 \times 75 + 153 \times 153}{3360 \times 18} = 2\frac{1}{2}.$$

Making a total sectional area of at least $60\frac{1}{2}$ square inches required when the columns are braced together so as to form one complete cylinder cantilever. Actual sectional area of the column is about 137 square inches, which is, therefore, more than sufficient.

In working the strains on the bracing, we must, for convenience, assume the guide-framing as reaching the full height of the holder, which would make it three bays. The reason for this being that the strain on the bottom set of diagonal ties is the same as if the guide-frame ran to the full height.

$$S_1 = \frac{24 d^2 + D^2}{10,000} = \frac{24 \times 75 \times 75 + 153 \times 153}{10,000} = 15\frac{3}{4} \text{ tons.}$$

This, increased in the proportion that the tie bears to the pitch, equals for the ties (or X) 25 tons, and for the struts (or Y) 19 tons.

$$1 + 2 + 3 = 6.$$

Upper ties = $\frac{2}{3}$ of 25 = $8\frac{1}{3}$ tons or (say) 2 sq. in. required.

Bottom ties = $\frac{3}{3}$ of 25 = 25 „ „ 3 „ „

Section allowed *upper tie* = $5 \times \frac{5}{8}$ flat „ $2\frac{1}{2}$ sq. in. effective.

„ „ *bottom* „ = $6 \times \frac{5}{8}$ „ „ 3 „ „

Thrust on struts = $6\frac{1}{2}$ and $9\frac{1}{2}$ tons respectively. The girders are amply strong to meet this.

NOTE P.

In gasholders of the cantilever type, which depend so much upon the efficiency of the bracing between the standards, the ties should, if they cannot take hold of both flanges of the standards (*i.e.*, front and back) attach to the *heavier* flange, if possible; otherwise the weaker flange has to transmit the force through the web to the strong one. It should be the reverse—*viz.*, what the strong flange cannot resist itself, it should pass on to the light.

WATER BY MEASURE.

By METER.

This is a question which is constantly being agitated in London, but nowhere else in the United Kingdom. Why this should be so, is not easily understood; seeing that the rates are now regulated by assessment, defined by the Water-Rate Definition Act, 1885, and backed by the Regulation of Powers Act, 1887. Surely the accumulated ignorance of our present legislators cannot be allowed to go farther in harassing Companies which have acquired parliamentary powers. The rates charged by the eight London Water Companies are now less than those of the Provincial Water Companies, and should satisfy even the most unprincipled and unscrupulous ratepayer.

Those who clamour for water by measure, can advance no reasonable argument in favour of the scheme, other than confiscation of the water companies' property, or, as stated by themselves, the acquisition of these valuable works by local authorities on behalf of the people. There is something more than money value in dispensing an ample supply of pure water. No money can determine its value in its relation to the prosperity of a town. The benefit to the population lies in the benefit conferred. It is true the majority of people find it hard to understand that water has a commercial value; but there is a far higher value attached to water than is usually understood when we say it is vended at (say) 1s. per 1000 gallons. It is not only a necessity, but a luxury; and must be paid for accordingly. Circumstances are so varied in different water-works, that it is difficult to make a rule to apply to every town; although it may be conceded that most water companies could supply large consumers by meter. The cost of the water is of secondary consideration; and we should rather encourage its use, and reduce the charge to a minimum, in order to promote its extended utilization for motors and other trade purposes. Many large consumers would prefer to pay a fixed price for all the water they use or waste; and I see no reason why this could not be allowed in numerous instances. An inspector of experience will not be much in error in his calculation of the quantity of water used in most of the stereotyped businesses requiring a meter; and it is gratifying to find how readily an arrangement may be made with men of business habits desiring such a supply. There is no doubt that the universal adoption of meters to every service would reduce the quantity of water supplied; but it is equally certain that it would reduce the revenue. Then the question arises, Why should water companies be compelled to adopt a measure calculated to cripple the value of the supply not only for domestic use, but for protection against fire? for if the company is obliged to lose 5 per cent. on its domestic supplies, it must be recouped in some other form, and a charge made for fire protection and sanitary uses.

There is another section of the community who insist on the

Fig. 39.

use of meters; their avowed object being to check the enormous waste of water. This, however, can be accomplished effectively, speedily, and economically by present methods, and is not a factor in the argument. The consumption may be brought down to 20 gallons per head per day by house-to-house inspection; employing night inspectors who are appointed to separate districts. This is no new system, but was carried out thirty years ago, precisely in the same manner as described by "Inspector" in the JOURNAL for March 20 last; and so it need not be again explained here. There is much misunderstanding in the term "house-to-house inspection." It does not mean visiting each house in the day-time; that would simply be waste of time and money, as well as an annoyance to ratepayers whose fittings are in good order. It means a night inspection, and taking a record of all leaks discovered after midnight, when it may reasonably be conjectured that all use of water is at a standstill. Then during the day the only houses visited are those where waste has previously been suspected. Of course, where water is pumped, every gallon has a certain value; and waste must be restricted in the most efficient manner. Take a town of 30,000 inhabitants, and divide it into five districts, each commanded by any kind of meter; the whole of the houses can be visited by two inspectors during a fortnight, and then the round commences anew. It may be done even quicker than this; for by finding one or other of the districts consuming only two or three gallons per head, these may be left, and the inspector may proceed to investigate other districts where the greater waste is taking place.

It is stated that checking waste prevents the necessity of laying out large sums of money for extension of works; but this assertion is always made in the interest of some new meter or system of checking undue consumption. Plymouth has required an increased quantity of water for some time past; and the meter advocates claim that a supply by meter would be the remedy. But if we take the population at 100,000, and supply meters to each service at a cost of £50,000, added to which there must still be meters for checking waste, *plus* also the interest on first cost, the cost for repairs, maintenance, inspection, and extra collection, &c., it will then be seen that the additional storage reservoir contemplated will necessitate a smaller outlay. Which is the preferable plan? The Council have wisely decided to adopt the latter; for if it costs a greater sum to effect a saving of a few gallons per head than to procure an efficient supply for an important town, there can be no two opinions as to the desirability of procuring an adequate supply, which will not only meet the present difficulty, but give an ample supply for the future. Check waste by all means, but do it in the cheapest and most efficient manner as previously described; at the same time provide an ample supply for many years to come, and before the inhabitants are restricted to an intermittent service. Water is not unlimited in its supply; and this fact will be realized sooner perhaps than many people anticipate. There is therefore the greater necessity for checking waste and increasing storage, and keeping well abreast of the demands. Then, if waste can be so easily discovered and checked efficiently and economically, it cannot be advanced as an argument in favour of a supply by meter; for it is evident that meters cannot be applied universally and indiscriminately. There cannot be hard-and-fast lines laid down for the guidance of all companies. Each must be allowed to arrange its own business, to adopt the charges and use of meters where required, and to meet the peculiarities of the supply after extended tests and experiments.

The meter-rents at present charged are mostly too low. If a minimum rate is to be made, it must be in excess of the maximum quantity used by each class of houses proposed to be metered; and then there will be a profit earned from those who do not use the maximum quantity. If meters should be universally applied, water companies should be protected by a minimum charge to pay for the wear and tear of the instrument, its first cost and necessary inspection, reading, account-keeping, and incidental expenses, as well as the cost of conveying the water to the consumer's premises. It is reasonable to suppose that if a minimum rate for water, and a minimum rate for the instrument is to be imposed on the companies, that the amount of such rating would be submitted to competent judges, engineers of experience in water-works management and construction, and not placed in the hands of the Board of Trade. Each town should be considered apart; and its expenses, capabilities, and requirements weighed by those capable of discerning the merits of the case. One-half of the supply may be obtained from gravitation works, the first cost being the whole amount to be considered; whilst pumping from deep wells will be a continuous expense.

The meter that would be suitable for a town with a high-pressure supply would not be so for a town with a low-pressure supply, and carrying different ingredients in the water. The meter must be owned by the company, and kept in proper repair by them; the consumer being charged a reasonable rate for repairs, inspection, &c. The consumer, as a matter of course, would purchase, if allowed, the cheapest instrument in the market, regardless of quality or adaptability for the work; and after it is fixed a short time it would become useless and worn out. There should be a duplicate meter in stock to fix, whilst the old one is away for repairs, as the supply must of necessity be stopped until it is returned. But if in the wisdom of Parliament the consumer may be allowed to own the meter, it should be kept in repair by the company; the owner paying the charge. The company then would be in a position to fix another meter during the time the old one is being repaired and tested. The cost of the meter and its durability is a serious item in the calculation. Many meters

now in the market will not run more than six months without repairs, and are often rendered useless after two years continuous work. Take, for instance, a water containing a quantity of iron. In less than the time stated, the meter is corroded and set fast.

Again, the charges for rent of the meters will be fixed by the authorities; and the companies must abide by the decision of men who have had no experience. Five shillings per quarter is said to be the rent for a 2-inch meter—an instrument costing £24—which should be cleaned and repaired every year, and the life of which may be ten years. This payment for the hire of meters working under high pressure will not nearly compensate for the first outlay and maintenance. The question of payment for the use of the meters will give rise to further litigation in the Dobbs line; and that class of consumer will contend that the company have no right to charge for the use of the measure, it being a part of the works. We may just as well ask the consumer to assist in paying off the portion of the debentures that was raised to provide apparatus for pumping an efficient domestic supply. Again, you cannot claim to charge a minimum rate, as in some cases that would be charging for water the consumer had not used; and although Parliament granted a scale of charges to provincial water companies, they will be found only too willing to violate the enactment which should be held as sacred, and to introduce a fair "Bill" under which consumers will be charged only for the water they consume. This looks very well to the uninitiated.

The perfect meter, suitable for all situations, and capable of working under all conditions, has yet to be found. I often have brought under my notice "the most reliable meter ever invented." The patentee says he will leave it to the consumer to test it; and he is always sure it will stand anything in the way of ordinary work. I have generally found that these meters give out during the first day's trial; showing clearly that the inventor has no experience of actual water-works requirements. I had expected ere this that a report of the valuable tests of meters recently made at Manchester would have been published in the JOURNAL. It is understood that the "Uniform" meter came out the best for all purposes, and has been accepted. The chief tests were to work at 50 lbs. pressure; at full flow the meter to pass 10 gallons per hour; and the error to be within 2 per cent. The best meter is not that which measures water by drops, neither do I think it necessary that extreme accuracy should be sought, as against other requirements. In this connection, I may draw attention to the article on "The Testing of Meters" which appeared in the JOURNAL for Jan. 24 last.

(To be continued.)

GAS SUPPLY IN JAPAN.—We learn from Mr. Watson Smith, Lecturer in Chemical Technology at the Owens College, Manchester, that he has recently heard from his friend Mr. W. Newbigging (son of Mr. T. Newbigging, of Manchester), the Manager of the Tokio Gas Company, that the President of the Company—Mr. Shibusawa—has recently been enabled to announce that a substantial reduction in the price of gas will take place on the 1st prox. The President, in fact, states that the rate per 1000 cubic feet, which has hitherto been yen 3, will be reduced to yen 2.70, and that a discount of 5 per cent. will be allowed to consumers who pay over yen 30, 10 per cent. to those over yen 50, 12 per cent. to those over yen 100, and 15 per cent. to those over yen 150 per month. A "yen" is equal to about 2s. 9d. of English money. This surely points to good management; and, though an indirect compliment, is none the less a very practical and solid one to the care and skill of the Manager.

PRESENTATION TO MR. WALTER FIDDES, M. INST. C.E.—On the evening of Saturday, the 29th ult., a large deputation, representing the *employés* of the Bristol Gas Company waited upon Mr. Walter Fiddes, at his residence, for the purpose of presenting him with an address and a testimonial, on the occasion of his retirement from the Company's service. The address set forth the regret of the workmen at parting with their old chief, their appreciation of his character, and their best wishes for his future welfare. The testimonial was in the form of an elegantly wrought massive silver salver, bearing the following inscription:—"Presented to Walter Fiddes, Esq., C.E., M. Inst. C.E., M.I.M.E., by 512 workmen in the employ of the Bristol United Gaslight Company, as a token of their respect and esteem on his retirement from the post of Engineer after 44 years of service. September, 1888." Mr. Fiddes replied in a few kindly and well-chosen words, thanking all who had contributed to do him this unexpected honour. There was a slight error he went on to say, in the inscription on the salver, as he had been 48 instead of 44 years in the service of the Company. He acknowledged with pride and pleasure that in his work he always had the hearty co-operation of the *employés*, without which the best engineer would be valueless. The work had not been slight. When he "went into harness" the gasholders at the Company's works held but a few thousand cubic feet of gas; their aggregate storage power now, on his retirement, had reached several million cubic feet. He had seen introduced nearly all the great improvements that had been made in gas manufacture; and during his time the price of gas had been reduced to the extent of 6s. per 1000 cubic feet. In conclusion, he advised the deputation, and through them all the *employés*, to discharge their duties with the same fidelity, thoroughness, and union with those now over them as they had done in the past, and so build up and establish securely the interests of the great Company with which they were connected,

Technical Record.

GAS AT FIRES.

A short time since a congress of firemen was held at Fontainebleau, for the discussion of matters of special interest to members of this important branch of the public service. The proceedings were made interesting to the gas profession from the fact that a paper was read by M. Gustave Lefebvre, the officer in command of the brigade at Pontpoint (Oise), on "Gas at Fires," in which the author pointed out certain errors and absurdities contained in the code of rules compiled for the use of firemen. In so doing he gave his colleagues some sound advice as to how to deal with gas on the outbreak of fire; and although much that he told them has been put forward from time to time in this country by authorities on the subject—Captain Shaw and others—it may not be out of place to emphasize in our columns the statements of these gentlemen, by bringing to their support the opinions of a co-worker of a different nationality.

In the code of rules already referred to, it is very carefully explained in one of them that the medium usually employed for the production of light is coal gas; that this gas is conveyed from the place of manufacture to the point of consumption first by means of subterranean pipes of sheet iron coated with bituminous mastic, and subsequently by exterior pipes of lead; and that prior to being consumed it is measured by an appliance called a meter. All of these details were doubtless considered to be of vast importance by the compilers of the rules; but M. Lefebvre questioned—and very properly—their utility to a fireman, seeing that no particulars are given as to the appliances which are capable of producing accidents with which he might on some occasion find himself mixed up. This omission the author proceeded to supply; explaining the manner in which the pipes are laid in the streets, and the kinds of joints employed for mains and services, and indicating the places where leakages are likely to occur. The search for escapes in the trenches, he went on to remark, might cause accidents of which it was advisable that firemen should be forewarned. He pointed out that the escaping gas might be ignited by a main-layer's fire standing in the vicinity, by a lighted match carelessly thrown into the trench by a smoker, or by a gas-jet which happened to be burning; and he explained how the flame could be extinguished—viz., by means of earth or clay thrown upon it. In the open air, there was not, he said, much to fear from explosions; for a pipe charged with gas under pressure could not explode, nor could a gas-meter or a gasholder. Accidents, however, did happen; and although it was the duty of the gas company's servants to take all necessary precautions to ensure safety during their operations, and to deal with any outburst of fire that might occur, it was customary to call in the assistance of the fire brigade whenever the disaster assumed serious proportions, and it was therefore advisable for the men to be made acquainted with the dangers to which they were exposed. But he went on to say that the inflammable property of gas was not the only thing to be feared. Firemen should avoid breathing coal gas in large quantities; and therefore they could not with impunity remain at the bottom of a trench 6 or 7 feet deep where gas was escaping in sufficiently large quantities to immediately vitiate the whole of the surrounding atmosphere.

Having described the construction of a gas-meter, and the method of connecting it with the street main, the author remarked that a meter had been very erroneously regarded by many as a dangerous appliance—something liable to explode; but he assured his colleagues that there was no more danger in a meter while in use than there was in a gas-pipe or in a kitchen stove. The gas contained in a meter in operation is under a pressure ranging from 8-10ths to about 3 inches; and supposing anyone were to punch a hole in the case, and apply a light, no explosion would result. The gas would simply burn as at an ordinary jet, the meter would continue to act, and the gas consumed would be registered by the index in the usual way. But he reminded his colleagues that, in speaking of a meter as non-explosive, he had referred to a meter which was "in use." Of course, if the instrument was out of use for several days, or perhaps months, air might possibly find its way in, and, mingling with the gas, produce an explosive mixture, which, on the approach of a light, would ignite, and entail serious results. But was it under such exceptional conditions as these that a fireman would find himself in proximity to a gas-meter, supposing him to be called to a fire which had occurred in a building lighted by gas? Assuredly not. Consequently, if the fire were to break out during the daytime, and gas was not employed for lighting the cellars and underground portions of the building, the meter-tap might be turned off. If, on the contrary, the outbreak were to occur at night, the first thing to be done would be to have the meter-tap open, and profit by the light afforded by the gas to find the direction of the underground passages, the sources of water supply, and suitable spots for the location of the engines and the laying of the hose. In a fire, gas was an auxiliary, not an enemy. What a number of victims resulted from the cry raised "Turn off the gas!" on the occasion of the disastrous fire at the Opéra Comique! In the resulting darkness, how greatly intensified was the confusion, and how difficult it became to rescue the sufferers! What harm, asked the author, would the gas escaping from a few small pipes have done in the midst of such a fiery furnace as the body of the theatre presented? What good might it not have done in the passages, behind the doors, in the refreshment-room, on the staircases! But, unhappily, thanks to popular prejudice, as soon

as the cry of "Fire!" was heard, there was an almost simultaneous shout of "Turn off the gas!" and on the following morning the meters were actually found uninjured in their places. M. Lefebvre related an incident which had occurred to himself, to show the folly of extinguishing the gas at a fire. He was engaged with a number of firemen in the cellars of a building in which a fire had broken out. The men were working in the midst of dense acrid smoke, produced from smouldering rags, leather, and the fumes of various kinds of fat. A few gas-jets, scarcely visible through the smoke, afforded the men a certain amount of help; but suddenly the lights were extinguished. An over-zealous workman had succeeded in making his way, through the smoke and the streams of water issuing from the hose, to the gas-meter, which he had triumphantly shut off; returning from the feat thoroughly drenched, but proud of his achievement, and fully confident that he had saved the building. As a matter of fact, he had simply embarrassed the firemen in the discharge of their very heavy duties.

The author closed the portion of his paper of which the foregoing is an abstract by asking his audience whether the knowledge of such facts as those which he had just placed before them was not of far more practical value to them than being told, as they were in certain of their rules, all about the construction and working of a gas-meter—as to its internal mechanism, the action of its constituent parts, the necessity for its being fixed quite level, and so forth—all matters which would perhaps be interesting enough to a gas inspector, but certainly not to a fireman. He said he thought his colleagues would agree with him that such details might well be omitted, and the space occupied by more useful information.

Passing on to consider the subject of the extinction of ignited explosive mixtures, the author remarked that the instructions given to firemen as to the best method of dealing with escapes of gas were, to his mind, not altogether satisfactory. For example, they were told that whenever a fire is fed by means of an escape of gas, the service-pipe should be flattened by a blow, and the tap on the inlet-pipe closed. If the flow of gas cannot be prevented in this way, the burning gas must be extinguished with wet sponges, rags, putty, or earth. The author considered that it would be sufficient to flatten the pipe simply, without turning off the gas at the meter, if the fire occurred at night, and the staircases, passages, &c., were lighted by gas, inasmuch as the men, as already explained, would be assisted in their work by the light afforded. But the fireman of 1888, he went on to remark, needed information as to other illuminants than gas, seeing that petroleum and its derivatives are now largely used for lighting purposes. Beyond this, they should be acquainted to a certain extent with the nature of explosive mixtures, so as to be in a position to give satisfactory answers to any questions put to them by experts called in to investigate the circumstances attending some calamity caused by an outbreak of fire. Having dealt with this portion of his subject at great length, and given a number of formulæ (based on data furnished by Bunsen, Regnault, Favre and Silbermann, and others), the author stated, with regard to explosive mixtures of air and gas, that when the gas is present in the proportion of 8-75 per cent., a dangerous mixture is produced; but that air very highly charged with gas would lose its explosive property. Practically, therefore, there would be less danger when an escape of gas produced such an odour as to frighten everybody, than when there was merely a slight smell. Firemen, and other people besides, ought therefore to be on their guard against entering with a naked light any rooms where the odour of gas is distinctly perceptible, even though it may not be particularly strong. But while escapes of gas are attended with danger, the liability to explosion is infinitely greater wherever petroleum or similar vapours are present in considerable quantities. These vapours, being heavier than air, make their way towards the ground. Coal gas, on the other hand, is much lighter than air, and consequently rises towards the ceiling; and it would be there that the explosive mixture would be produced. Ignorance of these facts has occasionally caused the loss of a fireman's life; and therefore the author thought they should be more widely disseminated among his colleagues than hitherto.

THE ASSESSMENT OF GAS-WORKS.—As a proof of the value of resistance to excessive assessments, it may be mentioned that at Stockton-on-Tees the gas-works of the Corporation were proposed to be rated at £6175. Representatives of the Corporation recently attended before the Assessment Committee, when the latter offered to bring down the amount to £5500. Notice of appeal was given, when the Committee further offered to reduce the amount to £5250; and eventually it was fixed at £5100, or £1075 below the sum originally proposed. This result was achieved through the labours of Mr. T. Newbigging, C.E., of Manchester, who acted for the Corporation.

DEATH OF MR. J. H. SMITH, OF SUTTON-IN-ASHFIELD.—We regret to learn that Mr. James H. Smith, Manager of the gas and water undertakings of Sutton-in-Ashfield Local Board, died somewhat suddenly on Monday last week. He had not been in good health for some time; but had latterly been rather better than usual. On the day in question, he visited Mansfield on business, and, not feeling well, called on Mr. Williams, the Master of the Mansfield Workhouse; but almost immediately on his arrival, he ruptured a blood vessel, and died the same evening. Mr. Smith was about 40 years of age, and had held his position at Sutton for upwards of nine years. The sad event was referred to at the meeting of the Local Board last Friday, and a vote of condolence with his mother and friends was unanimously passed.

THE WATER-GAS PLANT AT THE LEEDS FORGE.

In the JOURNAL for July 17 last, when noticing the presentation of a testimonial to Mr. Samson Fox, C.E., the founder and Managing Director of the Leeds Forge Company, Limited, on attaining his fiftieth birthday, we mentioned that the room in which the event took place was lighted by water gas manufactured on the premises. As the Company claim to have been the first to introduce this kind of gas into this country from America, it may be interesting to give a few particulars as to the appliances employed, as contained in a description of the plant which has recently been issued by the Company.

It should be mentioned at the outset that the use of water gas for lighting purposes was not the primary object in view in installing the new plant at the Leeds Forge. Towards the close of last year, the exigencies of the metallurgical operations carried on there in connection with the manufacture of the corrugated boiler-plates, with which Mr. Fox's name is associated all over the world, demanded fuel of a higher calorific intensity than could be found in the generator gas obtained from the Siemens producer, or in the ordinary coal gas as supplied by the Corporation. Beyond this, the varying pressures at which the latter gas issued from the mains interfered seriously with the operations of the forge. Mr. Fox thereupon determined to have gas-works of his own, to be so arranged that the most suitable pressure for the work to be done should be constantly maintained, and that the supply should be bountiful. Water-gas plant, with which, we believe, Mr. Fox was very favourably impressed when on a recent visit to America, was therefore decided upon, and instructions given for its immediate erection. The works were commenced on Sept. 29, 1887; and on March 29, 1888, the plant, capable of producing 35,000 cubic feet of gas per hour, was started, and has been in constant operation since that date with perfect success. No alteration has been necessary to the then existing plant, beyond connecting the gas-pipes from the water-gas works to the several furnaces and machines. The plant consists of a generator, with means of producing an air-blast, and provided with the necessary valves; a scrubber to cool and cleanse the gas of dust; a small gasholder and purifiers in proportion to the amount of gas to be passed, and controlled by a centre-valve. A steam-boiler has to be added to the plant if there is not sufficient steam power already on the works.

It is scarcely necessary to describe the process of generating water gas, which, as is well known, consists simply in passing steam through incandescent carbonaceous matter. In the generator the water is decomposed into its elementary gases; the oxygen combining with the carbon to form carbonic oxide, while the hydrogen remains free. The combustible percentage of water gas is claimed to be about 95. In the apparatus for the production of the gas the principal part is the generator, in which, as already stated, fuel is raised to a high temperature by the aid of an air-blast. During this process, a gas commonly known as producer-gas—containing about 28 per cent. of combustible gas, mixed with the nitrogen of the atmosphere in the air-blast—is generated. When the fuel has become sufficiently hot, the air-blast is stopped, the outlet by which the producer gas has escaped is closed, the communication between the generator and the scrubber opened, and steam allowed to enter the generator. This, passing through the incandescent fuel, becomes decomposed, and a fixed gas, of the composition above stated, results. All these operations are easily effected; and there is no possibility of mistake on the part of the operator. The process lasts about four minutes, during which time something like 4500 cubic feet of gas are produced. From the generator the gas passes to the scrubber, and thence to the gas-holder, whence it is taken to the purifiers, which are of the ordinary type. The fuel employed may be the cheapest kind of coke, either mixed with coal or used alone; the consumption per hour per generator, when in full work, being about 10 cwt. The production of water gas per ton of fuel is 30,000 cubic feet; and each generator is capable of producing between 17,000 and 18,000 cubic feet per hour. The cost of the gas will depend upon the make, price of fuel, and of labour. With fuel at 8s. per ton, labour at 3s. 6d. per man per day, and the generator fully employed, the gas is stated to cost about 4·4d. per 1000 cubic feet.

As already mentioned, the water gas is used for lighting purposes on the works; the medium employed being the now well-known Fahnejelm "comb," which has been fully described in our columns. It is claimed that a saving to the extent of 50 per cent. has been effected in the cost of lighting by the adoption of the new gas; while, there being less heat, the atmosphere of the works is much more agreeable than under the arrangements previously existing.

The salary of Mr. Charles Nickson, Superintendent of the Gas Department of the Manchester Corporation, has just been increased by £50 per annum.

The Vienna correspondent of *Industries* has stated that for the electric light installations in the city—other than that of the Imperial Continental Gas Association for the Opera House, &c.—steam-engines of 1982-horse power and gas-engines of 393-horse power are employed. About 40 per cent. of the installations use gas-engines.

At the Salford County Court on Monday last week, the affairs of Mr. J. Graves, the absconding Town Clerk, to which reference has already been made, were again brought forward. The debtor was called, but did not answer. The Assistant Official Receiver thereupon applied for an adjournment of the matter *sine die*; and this was granted—a warrant being issued for the debtor's arrest.

Register of Patents.

PENTANE STANDARD LAMP.—Harcourt, A. G. V., of Oxford. No. 11,985; Sept. 3, 1887. [8d.]

In the JOURNAL for Feb. 28 last, we gave a general account of the construction of this lamp and the mode of its use; but by the publication of the patent specification, more specific particulars are available, and these we purpose giving to-day, illustrating them by means of two views of the lamp—sectional front and side views.

The lamp consists of a glass vessel A, mounted upon a stand B, provided with levelling screws C. To the vessel is fitted a cap D surmounted by a tube E, in which a wick is wound up and down by any ordinary arrangement of a double-spiked wheel F, turned by a handle. Around the upper part of this tube, whose diameter may be about $\frac{1}{4}$ inch and its length 6 or 7 inches, is a second tube G, about 1 inch in diameter and 4 inches in length, which serves as a jacket to keep more constant the temperature of the inner tube, and to guide the air current, upon which the steadiness and brightness of the flame depend. The two tubes are joined by flat plates H above and below, and constitute the burner of the lamp. Attached to the inner tube by branches, is a gallery J carrying a metal chimney K, which surrounds both the burner and the lower part of the flame. Above the burner, the part K1 of the chimney is reduced to a diameter intermediate between that of the outer tube G and the inner tube E of the burner; and it terminates at a short distance above the burner. The upper part of the flame is again enclosed by a continuation L of this metal chimney, which is of the same diameter as the lower part, but enlarged in diameter towards its upper end. This upper portion of the chimney is connected with the lower chimney by curved metal bands M—conveniently two in number, and sufficiently removed from the flame on either side as not to affect it. Through the space thus left between the upper and lower metal chimneys, the central part of the long flame which the burner produces is alone visible. The attachment of these bands connecting the upper to the lower chimney is adjustable by set-screws N, so that the opening through which the central part of the flame is seen may be made longer or smaller, as desired. By simple means (such as an adjustment screw, or preferably by means of cylindrical gauges of the same diameter as the tubes which they separate), this opening can be set quickly and accurately to such sizes as will give exactly the light of half-a-candle, one candle, one-and-a-half candles, or values intermediate between these, as required. At opposite sides of the lower part of the upper chimney are two narrow slots O, through either of which the tip of the flame may be seen; and the construction of the lamp is such that the light emitted through the opening between the two chimneys is the same whenever the tip of the flame appears opposite the slot, whether towards the lower or the upper end. The bands M connecting the two chimneys are half the width only of the tube that surrounds the flame. When the lamp is vertical, so that these bands are in a plane perpendicular to the horizontal bar of the photometer, a point in the plane containing the edges of the bands nearest to the photometric disc, midway between these edges, and at the height of the centre of the aperture through which the luminous flame is visible, is to be taken as that from which distances are to be measured. This point represents the zero of the usual photometer scale. In order to easily obtain the plane in which this point lies, two slots S are cut in the bands on the side nearest the disc; and into these slots a flat piece of metal fits, of the same thickness as the depth of the slots. The point from which distances are measured lies on the surface of this piece nearest to the disc. Suitable attachments are provided for carrying a plumb-line P, to serve in setting the lamp vertical, and for carrying a small piece of coloured glass fitting in the plumb-line socket T so as to stand opposite to the slot O. By reflection from, or direct vision through, this glass it may easily be observed when the tip of the flame is within the slot.

The height of the gauges that will produce, when burning "pentane," a light equivalent to a half, one, or one-and-a-half, standard English parliamentary candles, has been found by the patentee to be respectively 7½, 16, and 27·5 mm.

GASHOLDERS.—Gadd, W., and Mason, W. F., of Manchester. No. 13,521; Oct. 6, 1887. [8d.]

The specification of this now well-known invention—inasmuch as it has been frequently referred to in recent issues of the JOURNAL—appeared almost *verbatim* three weeks ago, pp. 503-4.

GAS-COCKS.—Foster, T., of Manchester. No. 14,939; Nov. 2, 1887. [6d.]

These improvements consist in the construction of a cock or tap that may be used independently of, or in combination with, an ordinary gas-

cock, for the purpose of enabling a small jet or flame, consuming a previously arranged fixed quantity of gas, to be left burning in workshops or other places during meals, or at times when the full amount of gas is not required. The object of the invention is to prevent waste of gas by a large flame being left uselessly burning, and also to avoid the risk of escape through carelessness by turning the gas-jet out and afterwards turning the tap on without the gas being ignited.

GAS COOKING-OVENS.—Greenwood, T., of Halifax. No. 12,236; Sept. 9, 1887. [11d.]

This invention relates to improvements on patent No. 12,460 of 1886; the patentee now finding that the two inner side plates of the oven do not require bolting to the snugs on the back plate, but only on the front edges of the snugs on the door-frame. The back plate too is constructed to slide into its place without bolting as in the former patent. Also all the inner plates are left free to expand or contract, as there is only a bolt at the bottom of each side plate, and at the bottom of the back outer plate, in such a position that it will accommodate itself to expansion and contraction.

IGNITING APPARATUS FOR GAS MOTORS.—Crossley, F. W., and Anderson, F. H., of Manchester. No. 15,010; Nov. 3, 1887. [8d.]

This invention relates to the construction and use of igniting apparatus for gas-engines, so arranged as to admit a portion only of the combustible charge into a tube heated externally by means of a flame kept constantly alight.

GAS-ENGINES.—Abel, C.D.; communicated from the Gas Motoren Fabrik Deutz, of Deutz, Germany. No. 17,108; Dec. 12, 1887. [8d.]

This invention relates to gas-engines, which operate with a cycle of four strokes—viz., a charging, a compression, a working, and an expelling stroke—such as engines of the "Otto" type.

In such engines, the slide that effects the ignition of the compressed charge, and the valve that allows the products of combustion to escape after the working stroke, have heretofore been worked by means of a counter-shaft driven at half the speed of the crank-shaft, in order that they may only operate respectively at the end of every alternate instroke and at the end of every alternate outstroke. According to the present invention, the counter-shaft is entirely dispensed with, and the igniting-slide and escape-valve are worked directly from the crank-shaft; the igniting-slide being driven by an eccentric or cam on the crank-shaft, so as to make a to-and-fro stroke at each revolution, while the escape-valve is worked by a cam on the crank-shaft so arranged as to be automatically slid to one side thereon at every second revolution, and thus only effect the opening of the escape-valve once every two revolutions. The arrangements employed for this purpose are applicable as well for horizontal as for vertical engines.

APPLICATIONS FOR LETTERS PATENT.

14,008.—ATKIN, H., "Improvements in making gas from coal or other bituminous or combustible substances." Sept. 29.

14,047.—BARKOWSKI, R., and ANDREWS, C. J. D. (for and on behalf of the Schülke Gas-Lamp Company, Limited), "An improved lighting apparatus for gas-lamps." Sept. 29.

14,049.—WALLWORK, R., and WELLS, A. C., "Improvements in connection with self-generating gas or vapour burners." Sept. 29.

14,105.—SUO, W. T., "An improved mode of and means for lighting by gas." Oct. 1.

14,174.—HUGHES, R. H. and R. S., "Improvements in gas-lamps." Oct. 2.

14,177.—CHANDLER, S., sen., CHANDLER, S., jun., and CHANDLER, J., "Improvements in and relating to lamps." Oct. 2.

14,198.—SMITH, S. F., "An improved combined ventilator and gas-bracket for walls." Oct. 3.

14,248.—CROSSLEY, F. W., HOLT, H. P., and ANDERSON, F. H., "An improvement in gas motor engines." Oct. 3.

14,261.—M'ALLEN, C. F. A., "Improvements in gas motor engines." Oct. 4.

14,266.—JOHNSON, A., "Oiling the screw of main gas-valves." Oct. 4.

14,283.—LUTHER, W. H., and ROSE, G., "Improvements in and relating to oil, vapour, or gas and air lamps for lighting and heating purposes." Oct. 4.

CARLISLE CORPORATION GAS AND WATER SUPPLY.—The accounts of the gas and water undertakings of the Carlisle Corporation for the year ending June 30 last will be submitted to the Town Council to-day. We learn that the gas profits amount to upwards of £800, and the water profits to £4300; and it is the intention of the Gas and Water Committee to make proposals to give the consumers some advantage from the continued and increased prosperity of the two undertakings. We understand they will propose to reduce the price of gas from 2s. 6d. to 2s. 3d. per 1000 cubic feet, and increase the current rate of discount upon the water accounts from 1½d. to 2d. in the shilling.

SALE OF SHARES IN THE SWANSEA GAS COMPANY.—An important sale, by Messrs. J. M. Leeder and Son, of shares in the Swansea Gas Company took place at the Mackworth Arms Hotel, Swansea, last Friday afternoon. There was a large attendance of buyers and others, who took a keen interest in the bids. The auctioneer referred to some articles adverse to the Company which had appeared in one of the local papers, and also to the contemplated lighting of some of the public lamps by electricity, which certain members of the Corporation threatened to introduce; but pointed out that with gas sold at 2s. 10½d. per 1000 cubic feet to the public, and at 3s. to private consumers, the shareholders of gas companies need not be soared or intimidated by such threats. They were made, he said, with the view of depreciating the Company's property, in order that the Corporation might at a not far distant date purchase the undertaking; but he assured them that the Company was governed and managed by competent and businesslike men, who were not to be frightened by the attacks of either the Corporation or the Press. He then proceeded to show that the present 7½ per cent. shares of £25 each were selling in the open market at from £40 to £41 each; and that, taking this as their value, the 7 per cent. shares to be then sold should realize £38 each. The shares were then put up in lots of four, and the first few realized £37 15s., £37 10s., and £37 per share. The remainder were sold at £35 10s. and £35 5s. per share; the latter price paying about 5 per cent. to the investor. The total amount realized was about £9000.

Correspondence.

[We are not responsible for the opinions expressed by Correspondents.]

THE COMPETITION OF OIL WITH GAS AMONG SMALL CONSUMERS.

SIR,—The Gas Committee of the Stratford-upon-Avon Corporation are very anxious to second my efforts to supply gas to cottagers and other small consumers where oil is our strongest competitor. For this purpose I am desirous of obtaining all the information I can, bearing upon the subject. As it is not so much a question of collecting the accounts as that of providing interior fittings upon which I wish information, I shall be glad to hear of any plan that has been adopted elsewhere, and found to work satisfactorily. It may be presumed that under our Local Act we possess the power to supply gas-fittings and carry out the work required in fitting up houses; but I anticipate a difficulty in arranging with the owners of property. An agreement would have to be entered into between the parties interested, by which the owner of the property would give permission to the Corporation to fix the necessary fittings, and also provide for the removal of the same at the wish of either party to the agreement. Upon this point I consider a clear understanding should exist. It would therefore be necessary that the agreement be very carefully drawn up to meet the various contingencies likely to arise. The question of paying a small rental for the hire of the fittings is also one to be dealt with. This I consider should be sufficient to pay the interest on the outlay and meet any charge which may occur for wear and tear and renewals.

Any information on the above question will, I am sure, be of interest to many other managers; as it is by adopting this or some similar plan that we shall be able to compete with the cheap oils now so generally used by occupiers of small houses.

Stratford-upon-Avon, Oct. 6, 1888.

J. S. CRANMER.

THE BOARD OF TRADE RETURNS FOR 1887.—THE NEW REGULATIONS AS TO GAS COMPANIES' CAPITAL.

SIR,—I shall feel much obliged if you will kindly permit me to state in the JOURNAL, in answer to numerous correspondents, that the above-mentioned returns are not yet ready, and I am unable to say when they may be expected. I have, however, ordered the usual number of copies; and immediately they are delivered to me, the subscribers to the Gas Companies' Association (or anyone else at the same time, upon giving me due notice) may rely upon receiving copies.

With your permission, I will avail myself of this opportunity to state, for the information of those Companies who contemplate applying to Parliament in the ensuing session, that the recent regulation of requiring all new capital to be sold by auction, together with the sliding scale, has introduced many irregularities into gas legislation which, until the Gas-Works Clauses Act is altered and enlarged, will require to be dealt with in the Special Acts. I have prepared a paper to show what these are, but it is too long to ask you to insert it, at this late hour, in to-morrow's issue; so I will trust to your indulgence for next.

Gas Companies' Association, Palace Chambers,
Westminster, S.W., Oct. 8, 1888.

W. LIVESLEY.

PIPE EXTRACTORS.

SIR,—In your issue of Sept. 13 you describe a "New Pipe Extractor;" but as we have had for a number of years a system of pipe extraction in use here which is I think equal, if not superior to that there described, your readers may be interested in hearing of it—more especially as you speak of the "ordinary process of cutting out," which I had previously supposed somewhat out of date. As for the appliance described in your columns, whilst no doubt it will serve its purpose well, I do not think it will be quite so speedy as the arrangement we use; there being a power to drive the joint off. I am afraid that in the case of turned and bored joints, with a recess in the front of the socket filled with lead, the process will be slow, as the force required to drive these joints is so great that either the clip will slip or the joint will not give way at all.

Our arrangement consists of a hydraulic jack working against a clip fixed on the pipe close to the shoulder of the next socket to the one to be driven. Against this clip a block of wood is laid on the pipe, to make up the distance between the clip and the foot of the hydraulic jack. The head of the jack works against the socket to be driven off; a half-inch packing being placed under it, so that the jack will not force the lead off with the socket. We are accustomed to raise and lower the pipe by the block, to aid in loosening the joint; working the jack while the pipe is being lowered. If the joint is an obstinate one, and does not drive off at once with the force of the jack, the loose end of the pipe is raised and lowered several times. But, contrary to the method described in your columns, we generally loosen the lowering screw of the jack when raising the pipe; thus allowing the upper side of the socket to slip back slightly, as we find this tends to loosen the lower side of the joint. In most cases the pipe is completely drawn at the first or second attempt; but sometimes the whole force of a 15-ton jack is required to drive off a 12-inch pipe.

In any case, however, the taking out of mains need only constitute a small fraction of the work when a large main has to be laid in the same trench. But if it is done by the process of cutting out, it cannot fail to be a "tedious business," and not only so but an unworkmanlike job when done.

Gas-Works, Burnley, Oct. 5, 1888.

JNO. P. LEATHER.

MODIFICATIONS OF HARCOURT'S COLOUR TEST.

SIR,—I have no wish to enter into a lengthened controversy with Mr. Hinks; but there are one or two points in his letter which require a little notice.

He says: "Does Mr. Greville really think that an unskilled person can more easily judge the colour of solutions to be of the same tint, or discriminate between a strong contrast such as a red and blue or a colourless liquid and a bright red liquid?" There is, of course, no doubt whatever that the latter discrimination is the easier; but this is only a partial statement of the case. What I really do think is that the original Harcourt test, taken as a whole, is less liable to error in the hands

of comparatively unskilled persons than the more essentially chemical methods advocated by Mr. Hicks.

With regard to the question of the absorption of sulphuretted hydrogen by aqueous solutions, I have found, as a result of several experiments, that a very appreciable volume of gas containing sulphuretted hydrogen has to be passed through 70 c.c. of distilled water before a stain is visible on even very delicate lead paper; the error being apparently the greatest where the amount of sulphuretted hydrogen is initially the highest. Mr. Hicks seems to think that "novelty" is due for the use of "gas normal solutions." If he wishes to claim novelty for altering the strength of a test solution already well-known to chemists, I suppose he must do so.

There is nothing further in Mr. Hicks's letter calling for comment from me, except that I regret that he has chosen to assume that my recent criticisms of his apparatus are due to the fact of my having myself introduced some modifications of the Harcourt test. I can only assure Mr. Hicks that personal considerations of this character have not exerted the least influence over my conduct. Mr. Hicks writes, when alluding to my article: "He says in effect that my apparatus does not come up to his modification of Harcourt's colour test." What I did say was that I did not regard Mr. Hicks's apparatus as a modification of the Harcourt colour test; and this opinion I still adhere to. Mr. Hicks adds: "This, however, is only a matter of opinion from a not unprejudiced source, which each reader of the JOURNAL will better decide for himself." I entirely assent to this as an abstract proposition; for it applies equally well to Mr. Hicks as to myself. The whole discussion is, of course, in a sense, much a matter of opinion. Mr. Hicks will form his, being an engineer; I have formed mine, being only a chemist.

H. LEICESTER GREVILLE.

Commercial Gas Company, Stepney, Oct. 6, 1888.

THE OIL LIGHTING AT ERITH.—The oil lighting at Erith still occasions many complaints. Although the light is fairly good, one may walk about the district when the lights should be in use, and find many of them not burning. Messrs. Defries, the contractors, contend that this is caused by interference with the lamps; but the Lighting Committee will not admit this to be the case, and attribute the non-illumination to the want of proper organization in carrying out the contract. If the lamps are in future found unlighted between the specified hours, the Board intend putting in force the penal clauses of the contract.

THE PUBLIC LIGHTING OF STROUD.—At the meeting of the Stroud Local Board last Thursday, a letter was read from the Stroud Gas Company, in reply to one from the Board asking for a reduction in the charges made for lighting public lamps. The Company consented to make a reduction of 3s. a year on the ordinary lamps, but stated that they could not allow any abatement as regards the Sugg lamps. If the lamps lighted at present only six months, at a charge of £2, were lighted for eight months, an extra 10s. for each lamp would be charged. A discussion ensued; and it was ultimately decided to light all the lamps, including about forty to be erected, all the year round; the increased cost being stated at £40.

THE PUBLIC LIGHTING OF MAIDSTONE.—At the meeting of the Maidstone Local Board last Thursday, Mr. Barker stated that great complaints had been made in the town as to the quality of the gas, and the high price charged by the Company for the public lighting. Alderman Doe thought it was quite time the Board took steps to see whether the street-lamps were supplied with gas of proper illuminating power. For some time past he had noticed the poor light afforded by the lamps. In certain thoroughfares they gave such a dim light that he scarcely saw them. He contended that as the Board paid a large sum for the public lighting, they ought to have the work done properly. It was resolved that a Committee should be appointed to consider the matter.

THE GLOSSOP TOWN COUNCIL AND THE PRICE OF GAS.—At a meeting of the Lighting Committee of the Glossop Town Council held last Wednesday, a communication was read from the Gas Company respecting the gas burned by five special lamps for the past six years, which had been supplied gratuitously to the Corporation, and was considered equal to a gift of £60 per annum. The Company proposed to withdraw from this arrangement. They also stated their intention to reduce the price of gas consumed in the street-lamps 1d. per 1000 feet, and 2d. per 1000 feet for the gas used in the Town Hall and offices. The letter was discussed, and it was decided that a meter should be attached to one of the special lamps, to see what quantity of gas was burned.

THE NORTHERN COAL TRADE.—There is decidedly more activity in the coal trade of the North, and the tendency is towards higher prices, whilst the possibility of strikes in other coal-fields is likely to bring orders here. For steam coal, the demand is better; and the approach of the closing of some of the Baltic ports makes shippers anxious to get cargoes away. In the gas coal trade many of the collieries are hampered by the restriction which some of the workmen practise; and thus, having less coal to sell, they more readily obtain the higher prices they have asked of late. The demand for gas coal is still improving, and must be expected to do so for some two months yet; but the export demand for the North will fall off soon. Manufacturing coals are dearer all round. The activity at the shipbuilding yards is causing a larger consumption of fuel, and it is also stimulating the production of iron, which is one of the largest contributors to the prosperity of the coal trade. Generally speaking, coal in the northern district promises to be from 4d. to 1s. per ton dearer for next year's supplies.

THE PRICE OF GAS IN THE MANCHESTER OUT-TOWNSHIPS.—At the meeting of the Levenshulme Local Board on Monday last week, the Chairman (Mr. J. M. Pollitt) reported that, in company with the Clerk, he met the representatives of the various Local Boards supplied with gas by the Manchester Corporation. From figures submitted, it appeared that the Corporation were making a very large profit. So far as the out-townships alone were concerned, the sum charged by the Gas Committee for the gas supplied beyond the city, including street-lamps, was £103,775; and of this it was estimated that no less a sum than £26,650 was profit. Taking the city and suburbs together, it appeared that after allowing £33,623 for depreciation and £29,832 for interest, there remained a net profit of £76,240; so that it was quite clear that the Corporation had ample funds at their disposal to make a very considerable reduction in the price charged. The opinion of the meeting seemed to be that unless the Corporation met them in a satisfactory manner, it would be the wisest policy for the various Local Boards to make their own gas, singly or in groups, according to position. When it was shown that a town like Bury could supply gas at 2s. per 1000 cubic feet and make a profit, it was clear that other large districts around Manchester could do so on the same terms; and it would be folly to go on paying 3s. 2d. to the Corporation if gas could be produced at 2s.

Miscellaneous News.

COMMERCIAL GAS COMPANY.

The Ordinary Half-Yearly Meeting of this Company was held last Friday, at the Cannon Street Hotel.—Mr. R. BRADSHAW in the chair.

The SECRETARY (Mr. H. D. Ellis) read the notice convening the meeting; and the Directors' report and the statement of accounts, the principal portions of which were given in the JOURNAL last week (p. 596), were taken as read.

The CHAIRMAN: Gentlemen, the resolution which I have now to propose is—"That the report and accounts be read and adopted, and entered on the minutes." In moving this resolution, it is usual to make a few remarks; but I am compelled to ask your indulgence to-day. I have been suffering from illness for a considerable time—an illness which prevented me from presiding at your meeting in April last—and it is of a nature which very much affects my breath, and consequently, my power of speaking. Although, therefore, it has never been my custom to trouble you at any great length, yet to-day you must excuse me if I am even shorter than usual. Happily, there is nothing for me to say. But before dealing with the report and accounts, it is my painful duty to announce the death of our colleague Mr. Griffith Thomas, who was lately the Deputy-Chairman of this Company. His death has occurred very recently—since the report was printed. Mr. Thomas, as probably most of you are aware, was connected with this Company from its early stages—first, as a Solicitor, and subsequently as a Director; and his connection lasted from those early stages down to the day of his death. He was the last one left of the gentlemen who took part in the management of the Company in its early days. Though perhaps of late years he has not taken so prominent a part, yet, in days gone by, he rendered very great and valuable services to the Company. As a fact, I may state this—that he was connected with the Company when the £5 shares could be purchased at 2s. 6d. each. He lived to see the day when its £100 stock was quoted in the market at £281 10s. I am sure that the Directors have only anticipated your wish in passing, as they have done, a resolution, recording their appreciation of the services rendered by Mr. Thomas, and expressing their deep sympathy with the members of his family in the loss they have sustained. I have now the pleasure of announcing to you that your Directors have elected as the Deputy-Chairman of the Company my friend Mr. Ratcliff (cheers). This is an appointment I felt sure would meet with your most cordial approval. In turning to the report and accounts, I think I may venture to say that the latter are very satisfactory. I think I may say that they are more satisfactory than any accounts ever presented before. I think if you will refer to the accounts, and compare them with those of the corresponding period of 1887, you will find that every item of importance in the revenue account shows a gratifying increase; while, on the other hand, every item of importance in the expenditure shows a gratifying decrease. You will see that the gas sold amounted to 918,668,000 cubic feet, against 878,810,000 feet—an increase of 39,858,000 feet, or something in excess of 4½ per cent. There were 1017 tons more coals carbonized; the figures being 96,080 tons in the one half year and 95,063 tons in the other. The gas-rental—the most important item in the accounts, perhaps—produced £116,947, against £112,176; being an increase of £4771. Stove and meter rental showed an advance of £96, while residuals realized £37,523, as against £34,533—an increase of £2989, to which coke contributed £1589; breeze, £62; tar, £1026; and sulphate and ammoniacal liquor, £311. You see, therefore, this most gratifying feature—that there is an increase in every item mentioned; the gas-meter rental and every one of the residuals showing an increase. The miscellaneous receipts exhibit a small falling off of £100; but the result is that in the total receipts there is an increase of £7754—the figures being £157,308 in the present half year, against £149,553 in the corresponding period of the previous year. On the other side of the accounts, we find that the coals cost us £57,694, against £59,009—a saving of £1315, notwithstanding the larger quantity carbonized. It follows from this that the greater quantity cost less than the smaller quantity. I think the saving works out to between 4d. and 5d. a ton—nearly 5d. The other items in the manufacture of gas were pretty much the same as last time; there being a small saving of £208. The other items are very much the same. Distribution of gas cost £241 more; owing, no doubt to the larger quantity distributed. I am sorry to say that the bad debts showed an increase of £191. I think we are served by a very efficient staff of collectors, to whom we hold out every inducement to get in the accounts. Probably, some of the increase in this item is due to the bad times we are passing through, which we have had occasion to refer to in past half years; but in regard to which I think there are some signs of amendment. You will, I think, be glad to hear that the law costs were £30 less; and in the item of superannuation, we saved £125. The general result is this—that the receipts show an increase of £7755; and the expenditure a decrease of £1403. Putting these two sums together they amount to £9158, which represents the increase of net profit in the past half year, over and above the net profit made in the corresponding period of 1887. The question then arises, having earned this £52,166, what shall we do with it? We recommend the payment of a dividend of 13½ per cent. on the old and of 10½ per cent. on the new stock—the highest dividends we have ever asked you to accept. The payment of these dividends will absorb £44,800; and the debenture stock interest being also paid, there is a surplus left to be carried forward. That surplus, being added to the balance brought forward from previous half years, we have £49,765 to commence the present half year, if you agree to the payment of the dividends which the Directors recommend.

The DEPUTY-CHAIRMAN (Mr. T. W. Ratcliff) seconded the motion.

Mr. THORNTON asked whether the accounts could not be presented in such a way as to show the shareholders not only the results of the half-year's working to which they related, but also the figures of the corresponding period of the previous year. It would be a convenience to the shareholders to be able to compare the results of the two periods.

The CHAIRMAN: The accounts are in the statutory form. I do not know whether we have any right to do what you suggest. I know that they do it in some other gas companies and in railway companies. I do not know that there would be any objection to it; but if you had all information given to you, you would leave me nothing to say. (Laughter.)

The motion was carried unanimously.

On the motion of the CHAIRMAN, seconded by the DEPUTY-CHAIRMAN, the dividends recommended were agreed to.

Mr. COLEMAN, on the part of the shareholders and himself, congratulated the Directors on the results of the half-year's working, and joined with the Chairman in the sympathetic expressions he had used in reference to the loss which the Company had sustained by the death of Mr. Griffith Thomas. It had been said that no good could come out of the East-End of London; but what they had heard to-day proved that the contrary was the case. He was sure that they all approved of the appointment as Deputy-Chairman of their excellent friend Mr. Ratcliff—a gentleman he

had known throughout a long life connected with the East-End. In conclusion, he proposed a vote of thanks to the Chairman and Directors.

Mr. CECIL seconded the motion, which was unanimously adopted.

The CHAIRMAN: I beg to thank you, on my own behalf and on behalf of my colleagues, for this handsome vote of thanks which you have just proposed. I gather from what my friend Mr. Coleman says that he and the rest of the shareholders are very pleased by the report we present. I need not say it is gratifying to us to be able to present such a report. I trust that myself and colleagues may be spared for many half years to meet you; and I also hope that the accounts may not be less satisfactory than they have been to-day.

Mr. ENNIS referred to the handsome dividends which had been declared, and observed that it was supposed generally, that with such a dividend affairs were easily managed. Those, however, who were behind the scenes in a measure, and who knew something of the internal working, knew that a great undertaking like the Commercial Gas Company, really wanted watching in every sense. He proposed a vote of thanks to the officers for their services in the half year.

Mr. GOULD seconded the motion.

The CHAIRMAN: I have very much pleasure in "thirthing" the motion" and no one knows better than the Board that your officers thoroughly deserve this vote of thanks. Of course, we, as Directors, do the best we can for you; but we have to rely on our officers. I think I may say that no Company is better served by its officers than the Commercial Gas Company. Our Engineer has just returned from America. I do not know whether he has anything of interest to tell you.

The motion was heartily agreed to.

The ENGINEER (Mr. H. E. Jones, M. Inst. C.E.): I was about to say that perhaps I never deserved this vote so little as at the present moment; for I am only just back from a most charming holiday of a month's duration, for which I am indebted to the kind indulgence of the Directors, and which gave me an opportunity I have been looking forward to nearly all my life to visit the great continent of America. I have derived a great deal of personal pleasure from this visit; although I had to encounter in mid-ocean an equinoctial gale, which shortened my life by at least two days; for I got nothing in those two days but a great deal of tumbling about. I saw a few things in America which I am sure concern you all; and therefore, at the risk of boring you, I would like to say a few words on matters which apply to the special industry in which we are all concerned. I saw, in some of the remotest parts, away from the seaboard and the chief towns, like Boston and New York, not cities, but villages lighted by the electric light; and I saw at the same time in those villages a tremendous combustion of gas, and a considerable amount of oil being burned. I put myself in communication with the leading spirits connected with the supply of gas there; and I found that all these three industries are going forward together; and in the case of the most important gas-works I visited, their increase in the past year had been not less than 20 per cent. At the same time they admitted that there was a field for electricity; and one of its functions was to so intoxicate people with the luxury of light that they went straight off to the gas company and doubled their supply of gas. I came across another matter, on which I do not feel at liberty to dilate; but I do think my holiday will not be spent to your disadvantage. I came upon a process for the rapid development of gas of a high quality, which, as far as I can see at present, will most probably be of use even to an English Gas Company. It has to do with the ever-abounding and increasing supply of natural oil which is rising now in Russia as well as in America, and which tends now to alter very much the relations of the supply of light or the sale of any illuminating agents. I will not, however, go further now than to say that I see a means of adapting the cheap supply of oil which is coming very much to the front to the use and service of gas making.

The SECRETARY also returned thanks for the vote; and the proceedings then terminated.

ALLIANCE AND DUBLIN CONSUMERS' GAS COMPANY.

The Half-Yearly General Meeting of this Company was held on Saturday, the 29th ult.—Mr. E. FOTTELL, J.P., in the chair.

The SECRETARY (Mr. W. F. Cotton) having read the notice convening the meeting, the report of the Directors, an abstract of which was given in the JOURNAL last week, was taken as read.

The CHAIRMAN said the report and statement of accounts now presented compared very favourably with those for the corresponding period of last year. The shareholders would find in the accounts the exact figures for each department of the works; and therefore it would be unnecessary for him to go over them. He would, however, call their attention to the fact that there had been an increase in the quantity of gas supplied, which was extremely satisfactory. Since the last half year, there had been an increase of 183 in the number of their customers. This caused him very great pleasure, because it showed that, notwithstanding the opposition that might possibly be given to them, the public were pleased with the gas. As the shareholders knew, the Directors had in certain cases for some time allowed a discount to consumers using gas for other than illuminating purposes—that was to say, for gas-engines and for cooking. They had now come to the conclusion that in all cases where gas was being employed for these outside purposes, they would grant a reduction of 10 per cent. He believed that the adoption of this course would be the means of encouraging people to use gas; and, no doubt, the Company would reap a benefit from it during the current half year. With regard to the residual products, it was a matter for congratulation that to a certain extent there was an increase in the sale of tar and ammoniacal liquor, which was, he thought, a sign of a slight revival of trade. The principle on which they had sold the residual products was that of the sliding scale; so that whenever an improvement took place in trade which enhanced the value of these materials, the Company obtained an advance in the prices in proportion to that enhanced value. The sale of coke had not been so satisfactory. The demand was greater in other places than in Dublin; and although they had an inquiry for it from localities outside Dublin, they found it extremely difficult to get a freight that would enable them to deliver it. With this exception, everything had gone with the Company to their entire satisfaction. The shareholders were aware that they were now in the quarter for the reduction of the price of gas to 3s. 4d. per 1000 cubic feet. He had no doubt that the reduction of 2d. would cause an increase in the consumption of gas, and would yield a beneficial result. He should also call their attention to this—that in the coming half year they would have the advantage of the entire interest of the reserve fund to add to the profit and loss account, which would be in accordance with the Act of Parliament. He might add that the works were in a very satisfactory state. There was one thing he would allude to which he would rather have passed over in silence; but it was necessary, in order to keep themselves straight, that he should refer to the correspondence that had passed, and to the debates that had taken place at the Corporation meetings. As early as April last some speculatives were made there of a character which would certainly seem to be an attempt to place the Directors of the Company in an unfair light—in fact, they were accused of charging for more gas than they delivered.

That was a serious accusation. They at once contradicted it through a private letter from their Secretary, and not through the press; and the reply they received was to a certain extent an apology, and a statement that the assertions made were not borne out. But the charge had been repeated again and again; and, in fact, it had come to this—that it had been so often repeated that they were bound to notice it. In looking over the reports of what had taken place at the Corporation, he found that a Committee had been appointed to inspect the lighting of other cities, and that this Committee had reported that Dublin needed improvement, as its lighting compared unfavourably with other places. He wished to point out that in the towns which were compared with Dublin there were gas-lamps at every 50 yards. This, of course, gave a greater quantity of light; but the illuminating power of the Dublin lamps was quite as good. The Committee of the Corporation stated in their report: "We feel bound to observe that our city has need of improvement in this respect; the public lamps having the appearance of not being properly maintained, notwithstanding the heavy cost incurred." He did not know what the Committee meant by speaking of the "heavy cost incurred." Gas was supplied to the Corporation on the same terms as to private customers—they were charged exactly for the quantity of gas they consumed, and they themselves fixed the hours for lighting the lamps. The lamps were the property of the Company; and they were kept up at about half the cost the Corporation would have to pay for maintaining them. The Company supplied all the plant free; and the Corporation were charged merely for the repairs and painting. It was very unpleasant for him to have to refer to these things. The Company had been long maligned; and they were determined to put an end to these disputes between themselves and the Corporation. They had tried by interviews and by letters to bring about a settlement, but had failed. They had therefore come to the conclusion that they would alter the system of charging the Corporation for gas. They would give up the meter system, as the Corporation would not carry it out. The Company were allowed by Act of Parliament to make a contract for the lighting of the city. They had previously had such a contract; and they should go back to it again, for they saw nothing else in order to avoid the repetition of these troubles and annoyances with the Corporation. They should adopt this course in self-defence. If they did not come to proper terms with the Corporation, the Act of Parliament gave the Corporation the privilege of going before arbitrators, and having the matter settled. But the Directors were determined to go back to the old system. They would do this to avoid the conflicts that were going on, and which, instead of decreasing, were increasing. He would not say any more on the matter, for fear he might say too much. He believed there had been some other interest at the bottom of what had been done. By the time they met again, the system of their dealings with the Corporation would be changed. He concluded by moving the adoption of the report and accounts.

Mr. C. LALOR seconded the motion.

Mr. T. J. COTTON (the Corporation Lighting Inspector) said he would rather the task of answering the Chairman had fallen to a more suitable person than an officer of the Corporation. The Chairman had referred to the members of the Corporation; but he regretted that these gentlemen occupied the position of buyer and seller, and therefore were unable to answer him. This was an anomalous position for any member of the Corporation to be placed in; but so it always would be as long as the law stood as at present. Some of the observations of the Chairman were incorrect; and he questioned the good taste of introducing at all matters which were at present in dispute with the Corporation. It was perfectly well known that a large section of the Corporation were of opinion that the present state of things in the Gas Department must cease—that it was not free and independent. The Chairman had referred to circumstances that occurred several months ago, when an imputation was made against the Company. This was an imputation with which he never agreed, and did not agree up to the present time. The Chairman omitted to mention that the Corporation had called for an impartial inquiry, and asked for permission to test the regulating apparatus. How did the Company meet them? The Corporation asked for permission to test 200 or 300 governors, which would occupy a week or more. The Company, however, said that the Corporation should do nothing of the sort—that if the governors were tested at all, the whole of them should be tested, which would take three or four months to do. If the Company were anxious for an impartial inquiry, why did they not allow what the Corporation asked for? The position at the present time was that the lamps were the property of the Company, and not of the Corporation; and the Company said the Corporation had no right to touch them or to examine the apparatus by which the gas was measured. This, he maintained, was most unreasonable. Again, though the price of gas was reduced, the Corporation had to pay about 20 per cent. more than they had to do ten years ago. The Corporation were simply doing their duty in calling attention to these facts; and the Company, instead of meeting them as commercial men, met them with skilful reports and artfully concocted letters. Let them meet like business men. He did not mean to make any charge against the gentlemen of the Board. He did not think the Board would take any unfair advantage of the public or of the Corporation which represented the public; but he would say this—that the officers of the Company did not treat the Corporation like business men. A large section of the Corporation at present held the opinion that the officers of the Company regarded the Corporation as a great milk cow. This must be stopped. They should measure the gas correctly, so that they would not force the Corporation to take more than they wanted; and if their officers tried to make them take more, they would do nothing of the sort.

Mr. W. SPILLANE said the Chairman had omitted to say anything about the question of the coal contract. It was decided at the last meeting that the coals should be bought in the open market.

The CHAIRMAN acknowledged this was an omission on his part. He said the coals had been advertised and contracted for.

Mr. SPILLANE said he was aware that the coals were advertised for; but what he wanted to know was the terms of the contract.

The CHAIRMAN said he could not give any information as to the terms of the contract. He did not think any mercantile company should be called upon to disclose such a matter; and he would not do so. He might say that the cost of soft coal was 12s. 10d., and of cannel coal 15s. 6d. per ton.

Mr. SPILLANE said he was quite aware of the prices paid at present; but what he wanted to know was what would be paid for coals under the terms of the contract which would come into operation in October. A substantial reduction was to be made in the price of gas—to which he did not object, as it might be very wise economy to sell it as cheap as possible; but if they were to continue to keep up the dividend they must have a considerable reduction in the cost of coal. The reduction of 2d. per 1000 cubic feet of gas must be made up for in some other quarter; and it would amount to no less than £4000 or £5000 in the six months. He considered 12s. 10d. per ton an enormous price for soft coal in Dublin. Only ten days had been allowed for tendering for the supply of 300,000 tons of coal; and this was not nearly sufficient. In fact, he had been told by several English gentlemen that they had not had an opportunity of sending

in tenders. This he regarded as a grave error of judgment on the part of the Directors.

Mr. CORREY contended that the matter of the coal contracts was one on which the Directors surely ought to be allowed to use their own judgment; and he, for one, was confident they exercised it in the interest of the shareholders.

Mr. MILO BURKE remarked that Mr. Spillane no doubt took great interest in the Company's coal contracts; but he questioned whether his speech would do any good.

Mr. GUNN said they had had all this matter of the coal from Mr. Spillane at the last meeting, when he read the Directors a lecture which he (Mr. Gunn) did not know whether they deserved or not. Although Mr. Spillane was very severe, and told them a great deal about what they ought to do, he was very reticent as to his own transactions in another place. It would be very interesting to know the figure at which he succeeded in getting coal in Limerick. If he would furnish more details as to how he bought coal there—if he showed that he bought it considerably cheaper in Limerick, considering the greater cost of carriage, than it was obtained in Dublin, and disclose the name of the merchants from whom he bought it—then he would be giving some good advice. But to say that 12s. 10d. per ton was too much was not the proper way to treat the matter. He (Mr. Gunn) confessed that he did not know whether 12s. 10d. was too little or too much; but if Mr. Spillane or anyone else told them he bought coal at 11s. 10d. per ton, then he thought they would have reason to complain of the manner in which their business was being carried on. In the absence of any such statement, the shareholders must assume that the Directors were doing the very best for the Company, and that they were purchasing the coal at the lowest possible price. With regard to the observations of Mr. Cotton, he did not think that was a place for having a dispute of the sort. He denied Mr. Cotton's right as a shareholder to ventilate at that meeting the opinions he held as an officer of the Corporation. He had stated that the Corporation had been made to use more gas than they wanted; but the shareholders had also heard the statement of the Chairman, that the Corporation had the power of turning on and shutting off the gas themselves. He (Mr. Gunn) thought they shut it off too early. The fault rested with the Corporation. They ought to treat the public better, and keep the streets lighted longer. Surely the capital of Ireland had a right to be as well lighted as Manchester or any other large town in England. He noticed that the Chairman had said, with regard to the gas contract, that the Corporation could have the terms settled by arbitration. He hoped that the contract entered into by that means would be of a satisfactory character.

The CHAIRMAN said it was, perhaps, only right to set Mr. Spillane's mind at rest. He had great pleasure in assuring him that the price for coals under the contract would be less—he would say considerably less—than they were now paying; and, therefore, without venturing to prophesy, he might say there need be no apprehension as to the dividends being reduced.

Mr. T. J. COTTON, referring to the remarks of Mr. Gunn, said that, attending there as a shareholder, he wished to be in harmony with the meeting; but, on bearing what the Chairman said about the Corporation, he thought he had a right to reply to him.

The CHAIRMAN said with regard to Mr. Cotton's remarks as to the Corporation's gas contract, he thought it was not the time for a discussion of that sort. There had been a great deal of correspondence carried on, and personal rancour displayed in the matter; and the Board had come to a resolution to alter the system. If the Corporation then considered they were asked too much, the proper course would be to go to arbitration.

Mr. T. J. COTTON said the Company had no power to alter the system.

Mr. SPILLANE remarked that if there was any desire to hear the name of a place where the coals would be obtained cheaper, he could give it.

Mr. CLAY said this was not the question. The question was what Mr. Spillane was paying in his own case.

The CHAIRMAN said he knew a good deal about other gas undertakings as well as their own; and he was sure their contract for coals bore comparison with that of any other company, considering the position they were in. He defied anyone to assert to the contrary.

Mr. SPILLANE: I say that Cork is buying coal at 11s. per ton.

The motion was then put, and carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. Alderman WINSTANLEY, it was resolved that the dividends recommended—10½ per cent. per annum on the old shares, and 7½ per cent. per annum on the new—be declared.

A cordial vote of thanks having been accorded to the Chairman for presiding, and for his labours on behalf of the Company,

Mr. CLAFFEY proposed a similar vote to the officers; remarking that they were very efficient, and did all they could for the benefit of the shareholders.

Mr. CORREY seconded the proposition, which was carried.

Mr. W. F. COTTON having briefly returned thanks, the proceedings terminated.

SHEFFIELD UNITED GAS COMPANY.

The Ordinary Half-Yearly General Meeting of this Company was held on Monday last week—Sir F. T. MAPPIN, Bart., M.P., in the chair.

The LAW CLERK (Mr. W. WAKE) having read the notice convening the meeting, the report of the Directors, with the accounts for the six months ending June 30 last, an abstract of which appeared in the JOURNAL for the 18th ult., was presented.

The CHAIRMAN moved—"That the Directors' report be approved and entered on the Company's minutes, and that a copy of the resolutions of this meeting be sent to each shareholder." In doing so, he remarked that the shareholders would see that the report was a good one, and as satisfactory to them as it was to the Directors. They could not complain if they paid a dividend at the rate of 10 per cent. per annum for the half year, and had a surplus balance of £4029. They had placed £2895 11s. 7d. to the reserve fund (which was all they had power to put there), and the balance had been carried to the credit of the present half year; and therefore he was justified in saying that the report and accounts must be satisfactory to them all. He predicted on a former occasion that the Company would soon be in a better position than it was at that time; and this prediction had been verified. For the first half of 1887 they were able to add £1908 to the reserve fund; and for the second half, £1066. For the past six months they were able to complete that fund, and to carry forward a balance. The extension in the consumption of gas continued in the district pretty much the same as it had done for some years. During the past half year the Company had received £3037 more for gas than in the corresponding period of last year. Then meter and stove rents had been £167 more; and in the receipts for residuals, they had been equally successful. Coke had brought the Company £554 more; and the sales of tar had increased by £1311. The returns from the sale of sulphate of ammonia had increased by £1044. Thus their income had been considerably enhanced. On the other side of the accounts, they had had to expend £533 more for stokers' wages; repairs of various kinds to the works had cost £2593 more; repairs to

mains and streets, £832 more; and repairs of meters, £599 more—leaving the balance he had already named. From his observation and experience, he did not think that at the end of the current half year they would be in any worse position, but rather a better one. On several occasions a request had been made for a reduction in the price of gas in the Dore and Totley district. This request was brought before the Board at a meeting when the nominee Directors representing the Sheffield Town Council were present; and as they did not object, the Board had felt themselves in a position to grant the request. With regard to the quality of the gas, he believed it had been kept up to the same standard as hitherto. During the half year, 1038 tests had been made, which showed an average illuminating power of 16·20 candles; and if this had been calculated by the London standard burner, it would have equalled an illuminating power of 17·70 candles. The storage of the Company had been considerably increased, and was now equal to 8,280,900 cubic feet; but this was not quite a day's consumption sometimes, and further extensions would therefore be necessary in the immediate future. The number of meters out and in use on June 30 was 44,191. Of these 24,574 were 2-light and 8763 were 3-light meters; so that their business was on a very satisfactory and broad footing. They had so many customers that he did not think they would experience any very large reduction in the consumption of gas, whatever development took place in regard to electricity. On several occasions previously, he had urged users of gas to attend closely to their fittings; and he desired to repeat this advice. He was sorry to say that in the manufacture of gas they were still troubled with naphthalene. They had done all they could to discover the cause of this, and to remedy it. They had had the best advice, and experiments had been tried by the most eminent chemists in the country; but as yet the difficulty was unsolved, not only by the Sheffield Company, but also by a large number of other gas companies who suffered occasionally from this trouble. At one of the Company's stations nothing of the kind occurred; so that they transferred the coals that were used at the other works to this place, and still there was no complaint of it. The results were the same. At one of the works they appeared to produce it, and at the other they did not, whether they used the same or other coals. It was suggested—he believed by an old official of the Company, who had left their service—that the cause was that at one works they made more gas per ton of coal than at the other. But at the works where they produced the greatest quantity of gas per ton of coal, they did not find any naphthalene. Therefore this suggested cause was not the correct one. There was one subject he wished to mention, which he thought would have the hearty sympathy of the shareholders. They were bound at that time (perhaps it had been delayed too long—at all events it had been delayed long enough) to pay some compliment to their esteemed Law Clerk. All who knew what he had done for the Sheffield Gas Company must feel that this gentleman was entitled to some recognition. The Directors had considered that the best mode in which they could show their appreciation of Mr. Wake and his services was to have his portrait painted by some eminent artist and placed in the Board-room of the Company. The Directors did not intend to ask the shareholders to defray the expenses out of the funds of the Company, as they thought it would be a greater compliment to Mr. Wake to meet it in another way. The shareholders would be invited by circular to contribute to the fund, the subscription would be quite voluntary on their part, and be regarded as an expression of their good will to their esteemed friend. Having given a sketch of Mr. Wake's connection with the Company (which commenced in the year 1835), the Chairman said he thought the proprietors would have no hesitation in joining with the Board in presenting Mr. Wake with his portrait, and in asking him to allow it to be placed in the Board-room of the Company. With these remarks he begged to move the resolution he had read.

Sir H. STEPHENSON seconded the motion.

Mr. F. SIBBAY congratulated the shareholders on what he believed was one of the most satisfactory reports ever presented to any body of shareholders in that room. On behalf of the consumers of Dore and Totley, he thanked the Board for the concession they had made, and assured them that it would be heartily appreciated.

Mr. ROOME called attention to the statement in the report that a very large increase in the supply of meters had followed upon the decision of the Directors to put them gratuitously in the houses of consumers, and said it seemed that every effort made to supply the public was met by the public responding, to the advantage of the Company. They went largely into the supply on hire of gas cooking-stoves; and he asked if the same principle could not be applied to warming appliances for drawing, dining, and bed rooms. He thought such a plan would result in benefit to the public and also to the Company.

Mr. WILSON remarked that some misunderstanding existed with reference to the statement in the report as to the meters. Did the 1777 additional meters fixed during the past twelve months relate to new consumers, or did they simply replace old meters?

The CHAIRMAN said the meters were all for new consumers; and the 1777 favourably contrasted with the 678 additional meters which were fixed during the previous year. This, as Mr. Roome had remarked, was very much owing to the Company not charging for fixing; and the Directors anticipated such a result when they decided on making the change.

Mr. WILSON: Then it appears the electric light is not going to kill us.

The CHAIRMAN said no. The Directors would be glad, if they could, to carry out Mr. Roome's suggestion as to the use of gas-stoves in bed-rooms. Whenever it was possible, they would be glad to act upon any suggestion from the shareholders which would be for the benefit of the Company.

The motion was then put, and carried unanimously.

The CHAIRMAN next moved—"That the following dividends be now declared for the half year ending June 30—viz., 5 per cent. on the 'A' 'B' and 'C' stocks, and 6s. per share on the 'E' shares; and that the same be payable on Tuesday, the 2nd of October."

Mr. J. HOBSON seconded the motion, which was carried.

Messrs. Hobson, Harrison, and Blake were then re-elected Directors of the Company, and the business of the ordinary meeting concluded.

An extraordinary general meeting was then held, "for the purpose of obtaining the sanction of the shareholders to the creation and issuing of 20,116 shares of the nominal amount of £6 each, to be called 'D' shares; and for the purpose of passing such resolutions as may be necessary for effecting the aforesaid purpose."

The LAW CLERK having read the notice convening the meeting,

The CHAIRMAN moved a resolution sanctioning the issue of the shares; explaining that the Directors had deemed it advisable to exercise the powers already conferred upon them by Parliament and create the stock. They would be able to give to each holder of £100 stock—whether or not it had all been called up—three £6 shares; and they proposed to call up on each of them £1 4s. He would not predict the time when the Directors would make another call on the new shares; but they would certainly call up the whole of the "E" shares before doing so.

Mr. HOBSON seconded the motion, and it was agreed to.

A vote of thanks was then accorded to the Chairman, for the efficient service he had at all times rendered to the Company.

The CHAIRMAN said it was a great pleasure to him to preside at the Company's meetings, particularly when the Directors were able to satisfy the shareholders, as they had done, not only on that but on former occasions. The Directors secured the best scientific help they could get, and the best officers. They hoped their new Engineer, Mr. F. W. Stevenson, would give them as great satisfaction in the mode in which he would advise them as they anticipated from his knowledge and experience. He trusted that when they met on future occasions they would have the same satisfaction in their success and progress as they had had for many years past. He cordially thanked the proprietors for the compliment they had paid him, and his colleagues for their efforts on behalf of the Company. The proceedings then terminated.

EAST LONDON WATER-WORKS COMPANY.

The Half-Yearly Assembly of this Company was held last Tuesday, at the Offices, St. Helen's Place, E.C.—Mr. A. W. GADESSEN, J.P., D.L., in the chair.

The SECRETARY (Mr. I. A. Crookenden) read the notice convening the meeting; and it was decided to take as read the Directors' report and the statement of accounts (see *ante*, p. 519).

The CHAIRMAN: I now beg to make a few remarks upon the report; and I will make them as short as I possibly can. In the second paragraph of the report, you will see that the increase in the revenue is described as "moderately satisfactory." I, however, was going to ask you to regard the increase as very satisfactory. I think that the shareholders will take a rather more sanguine view of the matter than the Directors appear to have done. This word "moderately" has, I think, crept into the report through the ambitious views of our Secretary, who is very difficult to satisfy, and who is certainly not satisfied with small increases. The second part of that paragraph, however, qualifies the word "moderately," when it says, "having regard to the deplorable condition of some branches of industry in the Company's district." This reference is in allusion to the sugar-refining industry, those engaged in which were formerly large consumers of our water. In the last twelve months two refineries have been closed, which paid us between £4000 and £5000 a year. That is a large loss to the Company; but, notwithstanding, our revenue has increased. I would also draw attention to the fact that, at the close of 1887, the Company recovered revenue for purely domestic supply equal to that we enjoyed before those enterprising legislators, Messrs. Dobbs and Torrens, had entered upon their labours. I am pleased to tell you that our income from domestic supplies continues to advance, and that the increase in the half year ended Midsummer, 1888, as compared with the same period of the previous year, is just £2000; so that you may say that the increase which appears in our accounts of £2300 is almost entirely due to the additional domestic supplies. This, I think, is a satisfactory condition of things. Now, turning to the maintenance account, you see that the charges are rather less this half year than usual. This arises from two causes: First of all, we have enjoyed very great immunity from accidents to mains and machinery; and our maintenance charges have had the benefit of this. The decrease also arises in part from a charge for the fixing of hydrants for the Metropolitan Board of Works. Some of these expenses were incurred in the previous half year, but the whole credit for them has come into the present half year; accounting, in a measure, I think, for the decrease in the cost of maintenance. Then, with respect to the past half year, we may say we have been free from the anxiety we have experienced in former half years from lack of water—in fact, if we have had any anxiety at all in the past half year, it has been through our having had too much water. We have gone on very well indeed, as far as our water supply is concerned; and I am pleased to say that the quality of the water has also maintained the excellent character it gained in previous half years. The Secretary has put into my hands the report of the Registrar-General, who says: "The water, principally derived from the Lea, and distributed by the New River and East London Companies contained less organic matter than any of the Thames supplies. Both samples were clear and bright." I think that this is very satisfactory. The next matter I will trouble you with is a reference to the progress which is being made with our works. With respect to the Waltham Abbey works, I think you may consider them practically completed. The engines are fixed, and have been working admirably for some weeks—in fact, they leave nothing to be desired. I believe we shall get as large a duty out of these engines as has been obtained from any previously fixed by any Company. We have not quite done driving into the chalk, so as to get the largest supply we possibly can; but this will be accomplished, I daresay, in two or three weeks. Everything, therefore, is ready for putting the works into operation. With reference to the works at Lea Bridge, they are also proceeding satisfactorily. The engines are finished, and will be shortly at work; and the continuation of the sinking operations will be proceeded with as soon as we get the water out of the present shaft. These works promise an abundant supply of water. As to the works at Walthamstow, considerable difficulty has been experienced. They have not gone on so well as we had hoped; but there is nothing in the works themselves which presents any unusual difficulties. We have had some trouble in getting the cylinders down; but the work is now proceeding satisfactorily, and I think, in a comparatively short time, we may also get these works into operation. I may further state that the pumping of water from the gravel at Sunbury, which has been reported at previous meetings, is also giving very good results indeed. It is a valuable supply of water; and the volume is equal to slightly more than 2 million gallons daily. Altogether, therefore, you may consider that we are in a fairly satisfactory position. There is one point to which I must now refer, which is of a less pleasant character than the other matters I have spoken of. I allude to a case which appeared in the Police Court recently, and respecting which, perhaps, the shareholders may expect a few words from me. It was a case in which a man applied to us for a supply of water, and that supply was refused on account of there being no cistern attached to the house to receive the water.* I will just give the shareholders as clear a statement of the case as I possibly can. The Company require that every applicant for a supply of water shall provide a proper cistern to serve as a reserve of water. All our Acts involve this requirement. When Mr. Johnson applied, a survey of his house was made; and, no cistern being on the premises, we gave him the usual notice to fix one. This he refused, and eventually summoned the Company for non-supply. In addition to the proper cistern, every house must be provided with a water-closet service-box, and an efficient waste-preventing apparatus, so constructed as to be capable of discharging 2 gallons of water at each flush; and this flush practically empties the service-box. When the Magistrate heard the case, he maintained that this service-box, being, in effect, a cistern, no other was needed, and ruled that the plaintiff, having practically complied with the Act, we were in the wrong; and he inflicted a penalty of £5 for our neglect, together with the usual £1 per day for lack of water to an empty house,

and £1 1s. costs, together £15 1s. The effect of this decision would be, in case of failure of supply, which must occur occasionally through fires, repairs to mains and consumers' private fittings, that the house would be left without any water. It is to be regretted that the Solicitor representing the Company should have lost his temper when the Magistrate's decision was given. The remark made to the plaintiff was unfortunate; and the effect of the indiscretion has been, as it were, to place the Company in the wrong, whilst the wrongdoer, the plaintiff, is regarded as a martyr. We, of course, cannot leave the matter in its present state. We are going to appeal against the decision; and we think there can be no doubt as to the issue of the appeal. That is all I have to say at the present time. As I observed before, I myself regard the increase in our revenue as, under the circumstances, satisfactory. With respect to the resignation of our esteemed friend and colleague Mr. Mashiter, we are, of course, very sorry indeed that he should have thought that the time had arrived when he ought to retire; but he had made up his mind that he would do so, and we could not alter his decision. He has been a very valuable member of the Company for a great number of years, and his experience and past knowledge of its affairs were of considerable value to us. I can only repeat that we much regret his resignation. I will now move—"That the Directors' report and the accounts submitted to the meeting be received and adopted, and that, as recommended by the Directors, a dividend of £3 10s. per cent., less income-tax, on the ordinary stock of the Company, be declared, payable on the 12th of October."

Mr. HERBERT DALTON seconded the motion.

Mr. P. D. TUCKETT said he had no desire to make any remark in a hostile spirit; but some of the shareholders were a little disappointed at the dividend, for the accounts seemed to show that another $\frac{1}{2}$ per cent. had been made. It would only take a further £5000 to pay this addition to the amount proposed; but it was, of course, too late now. The revenue account, however, showed an increase of this amount as compared with the same period of the previous year, and there was a sum of £11,000 in hand. It was very nice that they were going to receive three dividends in one year; and they must all feel very much obliged to the Directors for the greater promptness displayed in paying the dividend. At the same time he did not think this was a sound reason for not declaring a larger dividend if this could be done. He believed that the proprietors were greatly indebted to the Directors and officers for managing the affairs of the Company as they had done, for otherwise they would not have gone on as well as they had, in spite of hostile legislation. Many proprietors, however, it should be remembered, had bought their stock by tender, and had given 190 per cent. for it, in the modest expectation that a $\frac{1}{2}$ per cent. dividend would be paid on it. Owing, however, to the adverse legislation to which the Chairman had referred, the dividends had been cut down to 7 per cent., which was barely $\frac{3}{4}$ per cent. on the price they had paid for the stock. He thought nothing should go forth which would lead to the supposition that the proprietors were in receipt of large dividends; and he hoped this was the last occasion on which they would have a distribution at the rate of 7 per cent.

Mr. F. TENDRON said he could not follow the figures of the previous speaker. The amount brought from the profit and loss account to the dividend and interest account was £73,000; and deducting interest on the debenture stock, they had a sum of £61,700 available. The proposed dividend would take £60,220, and there would only be a surplus of £1500 towards paying the additional $\frac{1}{2}$ per cent. suggested, whereas the sum required to pay such increase would be £4300. Nothing could be more unwise on the part of a Board of Directors than not only to draw upon a balance to pay a dividend larger than the amount earned, but to discount the future. They had no certainty, though they might hope to see the day when the Company would pay $7\frac{1}{2}$ per cent. It was very necessary for a Company like theirs to have a certain amount of undivided profit in hand. He thought that one reason why persons were ready to buy the stock of the Company at 200 was that 7 per cent. was reliable. He hoped the Directors would not think of paying more dividend until they were perfectly clear they could maintain the higher rate.

The CHAIRMAN: In reply to what has been said, I would point out that it would be injudicious in any Board of Directors to suggest an increase of dividend unless they saw their way to a continuation of it. The safest thing for a shareholder is to have whatever dividend he is pretty certain of receiving. Irregular dividends are very destructive to the success of any undertaking. I therefore think the Directors were perfectly right in proposing that we should pay the dividend we recommended, of 7 per cent.

The motion was carried unanimously.

Mr. TENDRON stated that he held the proxy of Mr. Bevan, of the firm of Barclay, Bevan, and Co., the bankers of Lombard Street, for the special purpose of proposing the election as a Director of Mr. Mashiter's son, Mr. Herbert Helme. Mr. Mashiter had been a Director for 39 years, and during that time had seen great changes in the history of the Company. He trusted that, in his retirement Mr. Mashiter would write his experiences—a proceeding which he was sure would be of great service to the Company. He scouted the idea of anyone stating that a water company had a monopoly. In the 39 years during which Mr. Mashiter had served them, the Company had also been enlarging their works, and they were that day proposing a dividend of 7 per cent. Was there any business in the City which had been successfully carried on for a period of 39 years, even allowing for vigorous competition, that paid so small a return? Water companies were great benefactors of the inhabitants; and he believed that a pamphlet of the kind to which he had already referred, written by Mr. Mashiter, would tend to convince the public that water companies were their servants and were benefiting the public largely. He did not believe that the attacks which were made on the water companies emanated from their customers, but that they came from a few men for political purposes, or that their assailants were agitators. He was glad to think that the Press was taking a more enlightened view of the duties of water companies.

Mr. ILSLEY seconded the motion.

Mr. ROKERY PRICE said he was very sorry that he felt it his duty to oppose the motion. He thought that a very serious principle was involved in the election—that a father should retire and his son succeed him. He proposed that the election of a Director be postponed till the next half-yearly meeting, so that sufficient time and opportunity might be afforded of finding a successor to Mr. Mashiter among the proprietors of the Company.

No one seconding the amendment,

The Chairman put the resolution, which was agreed to.

Mr. PRICE then proposed a vote of thanks to the Chairman and Directors for the able way in which they had conducted the business of the Company.

Mr. J. T. BLABY seconded the motion.

The CHAIRMAN having acknowledged the compliment,

Mr. ILSLEY proposed a vote of thanks to the officers.

The CHAIRMAN seconded the motion; observing that he could not speak too highly of their Engineer (Mr. W. B. Bryan, M.Inst. C.E.)

The motion was carried unanimously.

* A report of the case referred to was given in the JOURNAL for the 25th ult. (p. 555).—Ed., J. G. L.

Mr. BLABY: Is the money you intend to borrow to extend the works further?

The CHAIRMAN: I am much obliged to you for mentioning that matter. We have in hand certain works, and the money we propose to borrow will be for the purpose of finishing them. I hope the amount will be quite sufficient for the purpose.

The SECRETARY having returned thanks for the compliment paid to the officers of the Company the proceedings terminated.

THE SWANSEA CORPORATION AND THE GAS COMPANY.

THE TOWN TO BE LIGHTED BY ELECTRICITY.

In view of the decision come to by the Swansea Gas Company to raise the price of gas supplied for both public and private purposes, the Gas Committee of the Corporation, at their meeting last Tuesday, decided to recommend the Council to apply for a Provisional Order to light the town by means of electricity. At the outset it was explained that steps had been taken to see whether the right originally vested in the Corporation, by an Act of Parliament obtained in 1884, to erect gas-works in the town was still in force. The Town Clerk (Mr. J. Thomas), who, in accordance with instructions, had obtained Counsel's opinion on the subject, placed before the Committee the case he had submitted on the question to Mr. R. S. Wright. In the statement the Town Clerk stated: "There are existing in the borough of Swansea gas-works, the property of the Swansea Gaslight Company, and at present the Corporation pay the Gas Company a price per annum for the lighting of all the public street lamps in the borough. The Corporation are now desirous, in consequence of the high price charged by the Gas Company for gas, of erecting works themselves, and of lighting the public street lamps from such works." After recapitulating certain Acts of Parliament, the statement concludes: "Counsel is requested to advise generally as to the powers of the present Council of the borough of Swansea to establish gas-works under the powers of the Swansea Improvement Act, 1844, and more particularly upon the following points:—(1) Supposing the site for gas-works (two acres) under the powers of the Act of 1844 is too small, and Counsel is of opinion that there are no extended powers under the Public Health Act, 1875, allowing the Corporation to purchase other lands for this purpose, may the Council, having chosen, as site for the two acres, land adjoining their own property, utilize their own land in addition to the two acres for the purposes of gas-works? (2) Whether the Council have now the power reserved to the Local Board of Health by virtue of the Provisional Order to erect gas-works and apparatus, lay pipes, &c., and supply gas under the Swansea Improvement Act, 1844. (3) As to the powers of the Corporation to borrow money under the Public Health Act beyond the £15,000 authorized by the Swansea Improvement Act of 1844, sec. 49, giving power to borrow, being repealed. (4) Whether the powers of the Swansea Improvement Act as to lighting are confined to the old town and franchise, or whether the same have been extended by the Provisional Order incorporating the Public Health Act, 1848, and the Public Health Act, 1875, now replacing that Act. (5) Is it competent for the Council, under the provisions of 45 and 46 Vic., cap. 50, sec. 137, to make an order extending those powers to the whole of the borough?" The opinion of Counsel was in the following terms:—"I am of opinion that the powers conferred by sections 145 and 146, and following sections, of the Local Act of 1844, upon the Commissioners created by that Act are exercisable by the Council of the borough. This part of the Local Act was kept alive by the Provisional Order of 1850, which abolished the Commissioners, and repealed many of the provisions of the Act of 1844. The 5th section of the Provisional Order transfers the powers so preserved to the Corporation as Local Board of Health, and empowers the exercise of them by the Corporation in the same manner as if they had been powers granted by the Public Health Act, 1848. The Gas Company's Act of 1861, sec. 67, expressly saves all powers possessed by the Corporation as the Local Board of Health; and the effect of the Public Health Act, 1875 (see sections 313, 326, 341), is to preserve these powers to the Corporation as the Urban Sanitary Authority under that Act. As to the specific questions asked: (1) I am of opinion, having regard to the limit of two acres imposed by section 146 of the Local Act, and to the fact that no modification is introduced into that section by the Provisional Order of 1850, that the Corporation could not safely exercise for this purpose the general power of purchasing land conferred upon them by section 175 of the Public Health Act, 1875. But there will be little or no risk in their utilizing for gas-works' purposes land which is already their property, provided it was not purchased for, and has not been appropriated to, or held in trust for some other specific purpose. (2) For the reasons given above, I answer this question in the affirmative. (3) I am of opinion that the effect of sections 5 and 6 of the Provisional Order of 1850 is to place the Corporation, in executing the unrepealed provisions of the Local Act of 1844, in the same position, and to confer upon them the same powers as to borrowing, &c., as if they were executing the provisions of the Public Health Act. They may, therefore, with the sanction of the Local Government Board, exercise, for the purpose of carrying out their lighting powers under the Local Act, the borrowing powers conferred by section 233 of the Public Health Act, 1875. (4) I am of opinion that the lighting powers conferred by the Local Act of 1844 are extended by the Provisional Order of 1850 to the whole municipal borough. The powers are exercisable (by sections 145 and 146 of the Local Act) 'within the limits' of that Act. The section in the Act defining the limits (section 188) is repealed by the Provisional Order, which at the same time (section 1) defines the district of the Corporation, as the Local Board of Health for the purposes of the Public Health Act, to be the whole municipal borough, and (by section 5) makes the preserved powers under the Local Act exercisable by the Corporation as such Local Board in the same manner as if such powers had been granted by the Public Health Act. The effect is that both the old powers under the Local Act which are preserved, and the new powers given for the first time by the Public Health Act, are to be exercised by the same authority over the same area—viz., the municipal borough. (5) Section 137 of the Municipal Corporations Act, 1882, has, in my opinion, no application to the case. The Local Act which was in force in Swansea in 1835 was repealed in 1844; and its provisions cannot now be put in force." The Town Clerk also produced statistics showing the relative cost of lighting the town by means of gas, electricity, and oil. The cost of the two first-named illuminants was about the same; but offers to supply equal illuminating power by means of oil for about half the money were submitted. After some discussion, it was decided, as above stated, to recommend electricity.

EXMOUTH GAS COMPANY.—At the half-yearly meeting of this Company held last Saturday week, the Chairman (Mr. J. Sloman) congratulated the shareholders on the continued prosperity of the undertaking, and showed that, notwithstanding reduced prices, the earnings were larger than those of previous half years. He reported that the new gasholder, erected at a cost of £3000, was completed; and paid a high compliment to Mr. Willey, of Exeter, by whom the contract had been carried out.

THE CHARGES AGAINST THE HALIFAX GAS-WORKS OFFICIALS.

At the Meeting of the Halifax Town Council last Wednesday—the Mayor (Mr. Alderman J. Booth) in the chair—the charges which have lately been brought against certain of the officials of the Gas Department, and with the nature of which our readers are familiar, gave rise to a long discussion. Mr. W. Carr, the former Gas Engineer and Manager, was present, accompanied by his Solicitor (Mr. W. Storey); and there was a large attendance of the public.

Alderman RAMSDEN moved—"That the deed of indemnity [see *ante*, p. 586] now submitted, between the Mayor and Mr. Thomas King Fox, be approved, and the Mayor be authorized to execute the same on behalf of the Council; and that the Sub-Committee be requested to take all requisite steps in order to ensure a full investigation of the charges referred to."

Alderman J. W. BROADBENT seconded the motion.

Alderman LONGBOTTOM asked if there was to be a report upon the "gas scandal," and pointed out that the *agenda* paper mentioned a report of the Special Sub-Committee.

The Mayor said the Council were asked to sign something, as it were, *in camera*; but after it was signed he thought that an explanation would be given which would justify them in having passed a resolution of that sort.

Alderman LONGBOTTOM said he should not oppose the resolution, because it appeared to be the only alternative now left to the Council. He had previously been opposed to the signing of the indemnity, because he had thought that there was a more economical course open to the Corporation; but now he understood that the Sub-Committee were not able to get at any definite charges against any specific persons unless the indemnity was given. He only wished to point out the position into which they were about to be placed. The Council was putting itself in the hands of the legal adviser of a gentleman who might be prepared to spend any amount of money, seeing that the Corporation purse would be open to him. He wished to say, inasmuch as it had been stated outside the Council—he hoped it had not been said by any member—that he had been in favour of hushing up the scandal, that whoever had made that statement had said something that was entirely opposed to the truth. It had always been his wish that whoever might be the subject of these charges should be brought to book, and punished, if punishment were deserved, with the strongest penalty that could be inflicted. With regard to the indemnity, the fact that Mr. Fox would deposit a sum of £500 in the bank in the name of his solicitor and the Town Clerk, to await the issue of any action which might be taken against him, made a very considerable difference to the question of whether or not it was advisable to sign it; and he could not see that there was now any reason why they should not approve of the indemnity. He was told that certain charges were to be made and certain names were to be mentioned. He moved—"That if any member of the Council be named in the charges now about to be read by the Mayor in the matter of the gas scandal, such member be withdrawn from the Committee of the Council until such charges have been investigated."

Alderman RILEY (Chairman of the Gas Committee) seconded the motion and it was carried unanimously.

The Mayor then said that, before reading over the charges, he thought it was due to the Council that he should, in as few words as possible, give them a short history of the investigations which had been made with regard to the gas scandal. When Mr. Carr called upon him to say that it was his intention to send in his resignation, he (the Mayor) put the point to him clearly and distinctly. He said to him, "Why don't you commence an action against the *Pall Mall Gazette*, because in case you are non-suited through the fact that the law proceedings that you take would be abortive, it would cost you nothing, because I should pay the costs, and you would show to the public at large that you are trying to clear your character?" Mr. Carr replied, "If I thought the *Pall Mall Gazette* would not defend the action, I would at once commence proceedings; but I know that they would defend the action, and I am not prepared to go into the witness-box." He (the Mayor) then said, "But why should you fear to go into the witness-box? If there is nothing wrong, there is nothing for you to be afraid of." Mr. Carr replied, "Well, I have made up my mind that I shall resign; and I am not going into the box." Then he (the Mayor) said, "You are afraid to go into the witness-box;" and Mr. Carr replied, "Well, I am not going." He mentioned that conversation as an answer to a letter which had appeared in the papers, and which was calculated to throw dust in the eyes of the people, inasmuch as it defended Mr. Carr's course in refusing to take action on the ground that if he did so it would prove abortive. This was not the real reason why Mr. Carr had not commenced proceedings. Mr. Carr knew full well that they had information in their possession that he had been bribed to a considerable extent; and he (the Mayor) had no hesitation in saying that they could prove this statement up to the hilt. Going a little farther, he thought it would be a surprise to many members of the Corporation to be informed that they had contracted for a certain class of coal, and had received thousands of tons of coal of another and inferior quality, which had been paid for, though there was a difference of 2s. 6d. per ton in the price of the article contracted for and that supplied. This was not a mere hearsay statement. In order to satisfy himself of the truth of it, he had gone to the colliery and seen the coal being put into the trucks. He assured them that if it was possible to understand language at all, the contracts distinctly ordered a certain class of coal; and the Corporation were certainly not receiving the kind of coal ordered. In addition to this, as far as he could judge—though, of course, an investigation of the kind was a very difficult matter—the Corporation had paid for a very great quantity of coal that they had never received. When he informed them that only 1 per cent. of the coal, only one truck out of a hundred, had been weighed at the gas-works, he thought they would see at once that there had been—what should he call it?—gross neglect, gross and unbusinesslike conduct. The Corporation had a weighing-machine over which the trucks of coal had actually to go, and only one truck out of a hundred received had been weighed. Yet the advice-notes of the colliery company had been copied into the waggon-book just as they had been received; and this waggon-book had been sent forward to the Accountant. Of course, the advice-notes would correspond with the invoice; and when the invoices had come, they had been checked off by the waggon-book, and the account had been passed and paid. So that, as far as the weighing of the coal was concerned, the neglect in not weighing it opened, he considered, flood-gates for fraud and robbery. There was another thing that had caused some inconvenience, and that was with regard to the test-book, which should contain a record of the quality of the coal. He was told there was such a book, and it was a fact that they had the apparatus for testing the coal, and he supposed that it had been tested from time to time; but still they could not find any record of the testing of the coal which would guide them as to its quality. They found that out of 700 trucks of coal received from one colliery there had been five weighed (cries of "Shame"). He believed that when the particulars of other contracts had been gone over thoroughly—contracts of a similar character—they would find that they had been paying from 1s. to 1s. 6d. per ton more for coal than they could obtain the same quality for at other collieries. They hoped in a

short time to have analyses of the qualities of the coal they had been using, and other investigations were being made. The following letter had been received from Messrs. Godfrey Rhodes and Evans:—

*Commercial Bank Chambers, Halifax,
Oct. 2, 1888.*

Keighley Walton, Esq., Town Clerk.
Dear Sir,—As requested, we herewith send you the engrossment of the indemnity for execution by the Mayor. We also enclose the charges by Mr. Fox, duly signed, in separate sealed envelope, which has not to be opened or made use of until after the indemnity is signed. We shall be glad when giving notice of the charges to the parties concerned if you will draw their attention to the terms of the indemnity providing for any proceedings to be taken by civil action, and not by way of criminal information. We may say our client has reason for insisting upon this; otherwise he may be unable to give evidence of facts which are within his own knowledge. Please let us have your undertaking to send us the indemnity duly signed or to return us the sealed envelope enclosed unopened.—Yours truly,
(Signed) GODFREY RHODES AND EVANS.

He had just opened the sealed envelope, after signing the indemnity, and the charges were set out as follows:—

- (1) That William Carr, the Gas Manager, has received moneys by virtue of his position in relation to the Halifax Gas-Works, and has illegally appropriated the same to his own private purposes.
- (2) That Emor Green Wrigley, of Ashton-under-Lyne, has fraudulently substituted another and inferior coal for that which he had contracted to supply to Halifax and other gas-works.
- (3) That Alderman James Turner Riley, J.P., is unfit to occupy the chairmanship of the Gas Committee of the Halifax Corporation.
- (4) That the said William Carr, Emor Green Wrigley, and James Turner Riley have been guilty of malpractices in connection with the Halifax Gas-Works.

(Signed) THOS. KING FOX.

Alderman RILEY said he could only repeat what he had said in the Council Chamber two months ago. In respect of any malpractices, or in respect of any commission that had ever been paid on coal that had gone into the Halifax Gas-Works, he had never received sixpence in his life. If he had received a single sixpence, he had received a million of money. He made that assertion fearlessly, in the presence of forty gentlemen, with many of whom he had been associated for seventeen years. The Corporation had bought very large quantities of coal since he had been Chairman of the Committee; and there had never in his life been a single colliery proprietor, or a single representative of a colliery proprietor, who had said to him, "If you can influence the Gas Committee, and get my firm an order for coal, I will see that you are put in a position so that you shall not lose anything by it," or "I will give you money if you will do so." Never had such a thing happened in his experience; and he thought he ought to make that public statement in the interests of the gentlemen who owned the collieries. He only knew two gentlemen who supplied the Corporation with coal; and he most solemnly assured everyone there—and he asked them to believe him—that he had never received a sixpence, or had a sixpence offered to him, in his life for any such purpose as was suggested. He appealed to the Corporation to wait in respect to the charges and statements that had been put before them that day by the Mayor. And he would like to ask the Mayor if he had any objection to read the correspondence, showing the bungling way in which he (the Mayor) had gone about the matter—correspondence from the colliery proprietors relating to the quantity of coal which he (the Mayor) had stated had come from the collieries to the Corporation. With respect to Mr. Carr, he had stated two months ago that he chose to believe him to be free from corruption. He had been intimately acquainted with Mr. Carr for twelve years; and during the whole of that time he had never found him to be an untruthful man. When this scandal was first raised, he went to the gas-works, and had an interview with Mr. Carr, and had said to him, "Now, you and I have been associated in the management of these gas-works for many years, and I want you to give me a straightforward answer to a pointed question." He replied, "I will." He (Alderman Riley) said, "Have you ever received any commission on any coals which came into these works?" and Mr. Carr looked him straight in the face, and said, "I never have." A gentleman sitting on the aldermanic bench had similarly questioned Mr. Carr, and had received a similar reply. He preferred to believe Mr. Carr to be innocent of the charges until he was proved to be guilty. There were certain circumstances which had transpired that day which would possibly appear to put a different face upon the matter; but his desire was that the whole matter should be gone into. As to the quality of the coal, he did not take the slightest responsibility on that account. That was a question of manufacture. If the Council had been defrauded out of these large sums of money, all he could say was that he had been defrauded also, and most grossly deceived; but he did not take the slightest responsibility with regard to the quality of the coal. He had spent the best part of his life for twelve years in the work of the gas undertaking; and if he had had thousands of pounds invested in the concern, he could not have taken a greater interest in it than he had done. Whether they believed it or not, he assured them that this was true, and that he had been very proud of the progress of the works. When Mr. Carr first came to Halifax, the price of gas was 4s. per 1000 cubic feet, and now it was only 1s. 9d. per 1000. He thought these good results ought to be highly satisfactory to every member of the Council, and to every consumer of gas in the borough. As to the weighing of the coal, he had heard incidentally that a large proportion of the coal which was going into the gas-works was not weighed. He had expressed his surprise at that; and Mr. Carr had said that Mr. Cleasby would explain it. He (Alderman Riley) had tried several times to see Mr. Cleasby, but had not succeeded in doing so. He, however, understood that it had been to a large extent caused by the very short time that was allowed to Mr. Carr for taking the waggons into the sidings. Whether this would be a good and sufficient excuse to the Corporation remained to be seen. He again said emphatically to his colleagues in the Council, and to the rate-payers through the press—he emphatically said and swore there, before the Mayor and the whole of the Council—that he had never received a single sixpence, and had never had it offered to him by any colliery proprietor who had done business with the Halifax Corporation; and, further, he sincerely believed that the late Gas Manager, who was then sitting in the Council Chamber, had never received a sixpence in the shape of commission on coal or anything else.

The Mayor: What about Dempster?

Alderman RILEY said the Mayor should not ask him about that—he was talking about the coal. He would not believe that Mr. Carr had received anything until he was proved guilty. With regard to his own actions, he gave them a positive and serious denial of the charges; and surely he knew what he himself had done. He could not look anyone in that town in the face if he had done what was imputed to him, and could never put his head outside of his own house if he had told his colleagues in the Council a palpable and deliberate lie. He could only assure them, as he had assured the Mayor and the Town Clerk, that his hands were perfectly clean with regard to the matter.

Alderman LONGBOTTOM said that, however the statements made by Alderman Riley might come home to their own consciences, he was afraid they would not satisfy a great number of people outside the Council, in the face of the written statement that he (Alderman Riley) and other

persons had been guilty of malpractices. Therefore, the only course left to the Council, seeing that they had passed a resolution that the indemnity to Mr. Fox should be signed, was to pass another calling upon Alderman Riley to commence a civil action against the person who had made these charges against him. These charges were of the most serious, and, if untrue, the most scandalous character; and he should hardly think that any gentleman would have such a stigma as that attached to his name and character without justifying himself before "twelve good men and true." But he thought that, seeing that they had given an indemnity on one side, they should also give Alderman Riley a guarantee that if he brought an action, and succeeded in clearing his character, he should be nothing out of pocket thereby. As members of the Council, they should see to it that Alderman Riley did not suffer pecuniarily if he came through the ordeal with clean hands. He therefore moved—"That Alderman Riley be called upon to commence a civil action against Thomas King Fox, for the purpose of having the charges made against him fully investigated; and that, in the event of his obtaining a verdict in his favour, he be indemnified against all costs, charges, and expenses incurred by him in such action."

Alderman D. SMITH seconded the motion. He said he thought, in all fairness to his own character and to his standing in the town, Alderman Riley should take the course suggested, so that the matter might be fairly sifted.

The motion was carried.

The Mayor at this point referred to Alderman Riley's statement about his "bungling" in making inquiries at a certain colliery. He said he simply went down to inquire about a particular contract of which he did not know the exact quantity; and in asking them about it, he stated rather more than the quantity they had contracted for. He had said that the contract was for 8000 or 10,000 tons. Mr. Wrigley showed him that the contract was for 5000 tons, and that a second year's contract was for 6000 tons. He believed, however, that instead of the 5000 tons they would find that the Corporation had paid for more than 6000 tons. It was quite an irregular proceeding, when the Gas Committee had accepted a contract for 5000 tons, that 6000 tons should be supplied.

Alderman RILEY said he could explain that. He was sure the Mayor would not do or say anything wrong. (The Mayor: Not for the world.) They were under the necessity of ordering 1000 tons more; and the order was given with the consent and knowledge of the members of the Gas Committee.

The Mayor still persisted that such a course was irregular, and said the additional order ought to have been entered on the minutes of the Committee.

Alderman POLLARD said the charges were very serious ones; and it behoved them all to keep as calm as they could. He rose to propose that, in order not to keep the public in suspense on the subject, the Sub-Committee dealing with the matter should call the Council together every week or every fortnight to receive reports, now that they had signed the indemnity.

Mr. BROADBENT seconded the motion, but expressed the opinion that there was no necessity for it. The Mayor and his colleagues had not been at all dilatory, considering the work they had to do, and were doing it thoroughly. He suggested that they should be left unfettered; and they would, he was sure, at once call the Council together whenever they had anything to report.

Alderman LONGBOTTOM wanted to know what the members of the Gas Committee thought on the subject, and said they seemed to be as "dumb dogs" in regard to the matter.

Mr. J. W. DAVIS, as a member of the Committee, said his colleagues knew nothing of the alleged malpractices. He objected to Alderman Longbottom's observation that they were "dumb dogs" because they had said nothing with regard to the proceedings now going on. They were perfectly content to leave the matter with those in whose charge it was, and to await the result.

Mr. J. BROOK, another member of the Committee, supplemented Mr. Davis's remarks, and explained that during the last four months the weighing-machine at the gas-works had been out of order, and had been under repairs.

Mr. J. BAIRSTOW indignantly repudiated the appellation "dumb dogs."

Mr. J. BRANLEY said his great difficulty had been, on previous occasions when this matter was before the Council, to restrain himself from speaking; but now that they were challenged to speak, he would say one or two things. The duty of the Council was to believe all were innocent until they were found guilty; and he regretted that they should have departed from that course. The Gas Committee, had, he contended, not been treated with the courtesy which ought to have been displayed towards them. With respect to Mr. Carr, he was extremely sorry that the Mayor had felt it to be his duty to make him blacker than he was yet proved to be. He thought it was an injury to Mr. Carr. When the Gas Manager stated his decision to resign, he told the Mayor he was willing to stay at his post until his successor was appointed; and the Mayor replied, "Oh, you can go at once." He thought an old servant of the Corporation ought not to have been treated in that cavalier fashion. He had not approved of the indemnity—not that he would break any part of the inquiry, but he felt that if anyone had charges to make against a servant of the Corporation, they could make them without having an indemnity. He should believe both Alderman Riley and Mr. Carr to be innocent until they were found to be guilty; and he regretted that the Council should have been hounded on by libellous and slanderous things that had appeared in newspapers. So far as he knew the feelings of the members of the Gas Committee up to that moment, they had had, and they still had, the utmost confidence in the Gas Manager and in their Chairman, Alderman Riley.

Mr. L. CLAYTON also objected to Alderman Longbottom's expression "dumb dogs," and said the words must be offensive to each member of the Committee. He could only speak from his own experience on the Committee; and he must say he had found their proceedings had always been conducted in a businesslike and orderly manner (hear, hear).

Alderman LONGBOTTOM disclaimed any intention to be offensive, and described the expression used as a playful one, which he would at once withdraw.

The resolution was also withdrawn.

Mr. PEARSON suggested that the number of gentlemen forming the Sub-Committee should be increased.

The Mayor replied that he thought it would be the wisest course at present to leave the Sub-Committee as it was; if they required a greater number, they would not fail to ask the Council to increase it.

Mr. GRAYDON asked if all the books and papers which Mr. Carr had in his possession as Gas Manager were now in the hands of the Corporation.

The Mayor replied that the "test-book" referred to by him had not yet been found; but he could not at that stage answer Mr. Graydon's question.

The discussion then closed.

A meeting of the Gas Committee was held last Friday—when Mr. Binns, Vice-Chairman, presided. There were 38 applications for the post

of Gas Manager; the salary being £400 per annum. It was decided to consider these at a special meeting to be held on the following Wednesday (to-morrow). A letter was read from Mr. Carr, asking for a quarter's salary in lieu of three months' notice; and it was understood that the Committee would not entertain the application. Mr. Alderman Riley on Thursday placed the matter as affecting himself in the hands of his legal advisers, who are laying the charges before Counsel, with instructions to draw up an indemnity embodying the terms on which he would advise Mr. Riley to sue Mr. T. K. Fox. It is reported that Mr. Wrigley also has placed the matter in the hands of his solicitors, and intends to bring immediate action against the Mayor (Mr. Alderman Booth) for the libellous matter contained in his speech last Wednesday.

The following are some press comments on the matter:—*The Pall Mall Gazette* says: "We are very glad that the Halifax Town Council have found it out at last; but we put it to them whether they ought not, in common gratitude, to recognize the services which we have rendered to them." *The Leeds Mercury* says: "We are not disposed to accept the wholesale accusations which are made as true; but whenever they are specific, they should be traced home, and their truth or falsity established." *The Yorkshire Post*, referring to Mr. Fox's position, says: "The circumstance of any man entering upon any such undertaking under such conditions is a tolerably sufficient guarantee not only that he is in earnest, but that he has perfect confidence in his ability to make his words good, and to satisfy any Court of Law of the justice and truth of his statements." It is added by the *Post*: "The Committee will find it very difficult to persuade the public that their way of managing the gas business of the Municipality was as little blameworthy as they represent it to have been. What sort of management could that have been under which only one truck of coals out of every hundred received was weighed, so as to check the invoices sent from the collieries?"

The following letter has been sent to the local papers by Messrs. Storey and Co., Mr. Carr's solicitors:—"Sir,—As this matter [the Gas Scandal] will in all probability, and at no distant period, be thoroughly investigated in a Court of Law, we would again, on behalf of our client, Mr. Carr, ask the public, through your valuable paper, to suspend their judgment, notwithstanding the extraordinary statements that have been made in the Halifax Town Council Chamber and elsewhere. The course taken against our client so far will, on examination, be found to be unprecedented. The statements referred to are merely *ex parte*—that is to say, one-sided—and look as if they had been made on the principle of 'hanging a man first, and trying him afterwards.' Our client's position is strong enough to enable him to resist all attempts in the nature of coercion or despotic dictation; and as a Court of Law is to be appealed to, he will for the present refrain (however painful and trying the silence may be) from combating the statements made to his prejudice. With some people 'the wish is often father to the thought.' Fortunately, however, the thoughtful and charitable are in a majority, and, before forming a judgment, will, we venture to think, wait until both sides have been heard."

ROCHDALE CORPORATION GAS SUPPLY.

THE ALLEGATIONS RESPECTING THE GAS COAL CONTRACTS.

At the Meeting of the Rochdale Town Council last Thursday—the MAYOR (Mr. J. E. Petrie) presiding—there was a long discussion on the subject of the gas coal contracts. Certain charges, it may be remembered, had been made impugning the honesty of the Gas Committee in the letting of the contracts for coal; and, in accordance with a resolution of the Committee, the Chairman (Mr. Alderman Petrie) replied to the statements. The charges made by Mr. E. Evans at a public meeting on the 20th ult., as already reported in the JOURNAL, were (1) that the tenders were not dealt with, or entered into in a businesslike way; (2) that a member of the Gas Committee proposed that they should go to the Wigan Coal and Iron Company and do the best they could with them; and (3) that the very same class of coals as those accepted was offered by another tenderer at 1s. per ton less.

Alderman PETRIE said the proper answer to the last and most serious charge would be in a very short but unparliamentary word. It was absolutely false. The charge had arisen through the strange and unaccountable conduct of Mr. Parker, who was Mr. Evans's informant. This gentleman did not attempt to prove the allegations before the Committee; but expressed his very strong regret that he had ever spoken on the subject to Mr. Evans. He further told the Committee that the statements made by Mr. Evans were grossly exaggerated, and that he had given an interpretation to them—or had led other people to place an interpretation upon them—which he (Mr. Parker) had never for one moment intended to give. After this Mr. Parker promised the Committee that he would write to the papers on the Saturday following, showing the difference between him and Mr. Evans, and giving an explanation of the matter. But, to the surprise of the Committee, the real effect of the letter was most decidedly to confirm, and strongly confirm, the statements which Mr. Evans had made—putting him completely in the right, and repeating the statements in a more decisive and more offensive form. Proceeding to give the history of the transactions, Alderman Petrie said:—"So long ago as the 6th of June last the coal tenders were presented to the Committee and opened by them. The usual method was adopted; and the Assistant Town Clerk read over the particulars of each tender, and each member of the Committee copied the names of the tenderers and the particulars of their tenders as they were read out, so that he might have them before him for his private consideration. There were altogether no fewer than 34 tenders for different qualities and prices of coal; and this list they made out. A long and careful discussion took place, ranging over the whole of the tenders; and, as always happens in such a case, when we came to compare the prices, qualities, &c., a considerable number of tenders were set aside at once, for we saw that they did not represent the article we wanted. The 34 tenders were reduced to seven. The Committee felt that these were deserving of closer attention and fuller information, in order that they might all be thoroughly investigated. With this purpose a Sub-Committee was appointed, to obtain the best and fullest information they could on each class of coals tendered; and the seven tenders were handed to them. This Sub-Committee met five days afterwards, and set to work at the seven tenders. We collected the very best information we could; and, after going through the figures and results, we brought the seven tenders down to three. These tenders appeared to be very near each other. One of them was for the Arley Coal, and the price of it was 11d. per ton less than the coal we eventually accepted. The price offered was 8s. 4d. per ton, and the price of that which we bought was 9s. 8d. We were quite hoping that we had a coal that would beat anything we had had before. After carefully going into the figures, however, we found that this was not borne out. Although our best coal is 9s. 3d. per ton, we do not use that coal by itself. We mix two-thirds of it with one-third of nuts at 7s. 6d. per ton. This makes our coal for gas purposes 8s. 8d. per ton; but this is still 4d. per ton more than the tender to which I have referred. But from the very best information we obtained, we learnt that the new coal would only give us 17-candle gas. Our standard is 18-candle; and if we were to use that coal we should have to purchase

cannel to improve it, or else buy a much more expensive coal to mix with it. Then we were regretfully obliged to put that tender on one side also. If we had accepted it we should have been losers in the end. Thus we came down to two tenders. One of these was so near in the figures that although they only offered 5000 tons, we decided to test it, and if the test was satisfactory to purchase it. We at once ordered 100 tons, and tried them by a test over the whole works, and extending over two or three days. Fortunately the test was not satisfactory. The tender was then thrown aside, and we were left with one only. We had then to report our decision to the General Committee. There was another long discussion, and it was not without considering all the points that it was decided to give the order to the Wigan Coal and Iron Company. Only one member objected, and that member was Mr. Councillor Parker. After that had been decided, and not before, it was proposed that a deputation should go to the Wigan Coal and Iron Company, with full powers to do the best we could with them. That meant that we were to make the tender as much as we could at the price; and, if possible, to screw the price down a little as well. The deputation went to Wigan; and, after a very long struggle and some very hard bargaining, we got the price so modified as to make a saving of the round sum of £1000 on the whole weight of the tender. That was a pure saving to the rate-payers by the efforts of gentlemen whose character it is much the fashion to impugn at the present time. Between then and now we have had a number of Committee meetings and several Council meetings; but Mr. Parker has not thought proper to give the Council or the Committee the slightest idea that he objected to what was done by the Committee. In the letter which he sent to the papers (see *ante*, p. 600) he says: "My objection was to the position taken by a member of the Committee proposing that a deputation be appointed to wait upon the Wigan Coal and Iron Company 'to make the best terms they could before any of the other tenders were considered.'" This, Sir, is a statement which I hope no one will be found fool enough to believe, for it is absurdly untrue. He says further: "I protested against this proceeding, with the result that some slight consideration was given to a few of the other tenders." That also is a statement which can only cause the other members of the Committee to wonder how Mr. Parker can be possessed of such strange ideas, for they are fancies of a diseased imagination. I think I am justified in calling the conduct of Mr. Parker strange and unaccountable.

Mr. PARKER, in reply, said that when the tenders were opened, the motion that he complained of was made, and he was the only person who objected to it. He asked whether the deputation were going to the Wigan Coal and Iron Company to make the best bargain they could, when there was not one on the whole list who would not make some concession if appealed to. After this, they inquired into some of the tenders on his recommendation; but there were upwards of 20 different tenders that were never gone into at all. In the last there was one coal of a similar quality to the Arley mine coal at more than 1s. a ton less; and there was another coal advertised which would make 12,000 cubic feet of 18-candle gas, and would cost only 8d. more than they were paying. He did not know that he had said anything that he had any reason to retract. He had no intention of charging anyone with dishonesty in any shape or form; but if Mr. Evans so construed his statement, or put it in such a way that it might be so construed, he was a dishonourable man.

Several members of the Gas Committee vouched for the accuracy of Mr. Alderman Petrie's statement of what transpired, and warmly denied the allegations of Mr. Parker. It was suggested that a resolution of confidence in the Committee should be passed; but the Mayor and several members of the Committee thought that this was unnecessary, and it was not pressed.

Mr. PARKER, in a closing statement, said he told the Committee that if they gave the price quoted in the tender, they would be paying too much—that the price of coal quoted at Wigan, which, from a business point of view, was the pit price, was 6s. 6d., and that this, with the railway rate, 1s. 7d., and the cost of the waggon hire, 6d., should bring the coal up to only 8s. 7d. per ton.

Alderman PETRIE, in reply, expressed himself as well satisfied with the tone the discussion had taken. He did not remember the exact remarks of Mr. Parker in committee, but considered it quite possible he might have given them the information to which he had just referred. He had laid before them much information; and the Committee had listened with the greatest deference to what he had to say, because it was felt that, being connected as he was with the coal trade, his remarks ought to be attended to. He (Alderman Petrie) now thought they must attribute the whole of the misunderstanding to Mr. Parker being very excited when the Committee were considering the tenders. His imagination that the proposal to visit Wigan was made before the tenders were considered must have arisen from his being in a state of excitement.

Mr. PARKER: I cannot allow that.

Alderman PETRIE: If Mr. Parker remembers that the proposal was made, he must remember the name of the gentleman who made it.

Mr. PARKER: Then it was Alderman Baron.

Alderman BARON (warmly): That is so absurdly untrue that it needs no contradiction.

The discussion closed, and the minutes of the Committee were passed.

THE PRICE OF GAS AT ACCRINGTON.—The Watch and Cemetery Committee of the Accrington Corporation have lately been considering the desirability of approaching the Directors of the Gas and Water Company with a view of getting the price of gas supplied for the public lamps reduced; and the Town Clerk laid before the Committee a comparative statement of the price of gas supplied in all the boroughs in Lancashire. It was resolved that a table be prepared showing the high charge in Accrington; and the Chairman and one member were deputed to wait upon the Directors of the Company to ask them to reduce the price. Subsequently the deputation reported the result of their interview with the Directors, who had informed them that they had already under consideration the question of a general reduction, which might be adopted after the expiration of the year.

DISMISSAL OF THE HAWORTH GAS MANAGER.—At the meeting of the Haworth Local Board last Tuesday, a recommendation that the Gas Manager (Mr. M'Kenzie) have a months' notice to terminate his engagement was brought forward, and a motion for its adoption moved by Mr. H. Redman. He gave as his reason for doing so the thorough incompetency of Mr. M'Kenzie to properly conduct the works. It was some time before the motion found a seconder; but eventually Mr. J. Redman seconded it. Mr. M'Kenzie said he was totally ignorant that any charge was to be brought against him until the previous morning, when he saw the minute. All he had to say was that in every particular he had done as well as he could since he came to Haworth. After some discussion, the Chairman moved, as an amendment, that the Gas Manager be dismissed and that three months' notice be given to him; but there was no seconder to it. The motion was then put, when Messrs. H. Redman and J. Redman voted for, and the Chairman against it. The other members remained neutral. The motion was therefore carried.

BIRMINGHAM CORPORATION GAS SUPPLY.

INCREASE OF OFFICIALS' SALARIES.—WORKMEN'S HOLIDAYS.

At the Meeting of the Birmingham Town Council last Tuesday—the Mayor (Mr. Alderman Pollack) in the chair—the report of the Gas Committee, of which an abstract was given in the JOURNAL last week, was presented. The principal matters dealt with therein were, it may be remembered, the increase in the salaries of certain officials of the Gas Department and the granting of holidays to the workmen.

Mr. BISHOP, in moving the adoption of the report, said it had never been the practice of the Gas Committee to report increases of salary in the Gas Department, as it was treated as a commercial undertaking; but they had cheerfully complied with the resolution of the Council to prepare a report of all the advances which had been made during the current year. Having described the classes of officials to whom the advances referred, he said that since 1887 there had practically been no increase in the sum-total of the office salaries; while the management salaries had decreased. Alluding to the advance which had been made in the salary of one of the Engineers (Mr. C. Hunt), he said that, although only Mr. Hunt's name was mentioned, it was well known that there was a probability of Mr. Hack having his salary raised, so that the two might be taken together. It was thought by some that Mr. Hack was appointed since the undertakings of the Companies were taken over. This was a mistake. Both the Engineers were left as an inheritance to the Gas Committee—or rather they entered the service of the Corporation on the faith of certain promises made by those who negotiated the transfer. One promise was that their positions under the Corporation should be as good as they were likely to become under the Companies. It was then considered to be a great advantage to have both Engineers; and they had since proved to be of the greatest possible benefit to the undertaking. Mr. Joseph Chamberlain, at the time of the transfer, said the Corporation would do well to deal liberally with the Companies' servants; and after the first three years' experience of the Gas Committee, the right honourable gentleman gave the credit for what had been done to the Engineers in the first instance. He (Mr. Bishop) might be asked how the Committee justified the increase given to Mr. Hunt and the proposed increase to Mr. Hack. He would frankly acknowledge that, in his opinion, the Committee had made a mistake—(hear, hear)—not in the way suggested by the “hear, hear,” but in not giving the increase earlier, by gradations. Instead of allowing nine years to elapse without making Mr. Hunt any advance at all, they would have acted more wisely if they had made one three or four years earlier. But there were two reasons for the course adopted. One was that very extensive works were going on at Windsor Street, and the Committee were anxious to see whether or not they fulfilled the promises of the Engineers. Then the Committee were afflicted with the feeling caused by depression of trade, and were anxious to restrict expenditure as far as possible. In justice to the officers, it should be said that they did not press their claims for the same reason. Mr. Hunt had £800 a year when he entered the service of the Corporation. During the 13 years of his engagement, he had designed and superintended an extension of the works involving an outlay of £360,000. Surely, an advance of £400 during that 13 years was not excessive or extravagant. The works at Windsor Street had been approved by some of the best engineering authorities in the country as being admirably adapted to the requirements of gas making, and at the same time substantial and economic in their construction. Upon Mr. Hunt rested the responsibility of the work; and if the matter had been placed in the hands of an expert, the extra cost would have been £18,000. Similarly, Mr. Hack had carried out works at Saltley, which had cost £100,000; and the next extension at these works would probably be in about six or seven years' time, unless electricity did away with any need of an extension—and the Committee would not hesitate to entrust to Mr. Hack the responsibility of planning and carrying out such works. He wished briefly to refer to the saving effected in the manufacturing charges, in the increased production of gas per ton of coal carbonized, and in the prevention of leakage. The charges for which the Engineers were directly responsible had been gradually reduced at the Saltley works until they were lower by 13d. per 1000 cubic feet than they were in 1876, and at Windsor Street by 8d. At Saltley, the production of gas per ton of coal had been increased by 850 cubic feet; and at Windsor Street by 1200 cubic feet. This had been brought about without any deterioration in the quality of the gas; in fact, there had been an increase in the illuminating power. The leakage had been reduced by nearly 4 per cent.—a result that could not have been brought about without the skill and enthusiastic aid of the Engineers. The total annual savings he had mentioned amounted to £47,000; and in the face of these figures, he did not think the Council would have the ingratitude to complain of the increase. It was in the interest of the undertaking that the officials should be liberally paid. He would speak of the Secretary (Mr. Edwin Smith) last, as he was, after all, the principal official. Mr. Bishop related the circumstances connected with Mr. Smith's engagement, and spoke in most flattering terms of his services to the Corporation. He acknowledged that Mr. Smith had no previous experience of the work; but the promise made to him was that, if he should succeed, his financial position should be as good as any officer in the department, and if he failed he would have to leave at the end of the year without any consideration whatever. This was the pledge given by the Committee. Mr. Smith had not failed; he had more than answered the Committee's expectations. In the matter of bad debts alone he had saved the Corporation £2000 a year; for in 1877 the bad debts of the department were £3400, whereas in 1887 they were only £1400. The market price of such a man was beyond calculation; and he was worth to the gas undertaking far more than the salary paid to him by the Council. In conclusion, Mr. Bishop warned the Council against the mischief—he had almost said the folly—of discouraging their officers from putting forth their utmost energies on behalf of the Corporation they had served so well.

Mr. CLARKE thought the Chairman of the Gas Committee must have been romancing when he stated that £47,000 a year had been saved to the Committee when they handed over only £20,000 to £25,000 to the rates. The salary list was alarming, and wanted thorough investigation; and it was quite time the Council took the question of these salaries into their own hands, and did not continue the mistake of leaving the Committee to report after the advances were made.

Mr. GRANGER characterized the speech of the Chairman of the Committee as very remarkable and unwise. He was astonished to hear of the savings which it was stated had been effected; and he should like to know where the money had gone to. It had not gone into the pockets of the Corporation. The statements made now opened up the whole question that, from its formation to the present time, the Gas Committee had almost treated the Council with contempt—regarded them as enemies—and had tried to prevent the Council knowing what was going on at the gas-works. It was all very well to lay before the Council a lot of figures such as the Chairman of the Committee had produced; but they had nothing to compare them with. He believed the figures which had been adduced were altogether erroneous; and if the Gas Committee refused to give them proper returns, he hoped the Council would compel them to do it. As to the Engineers, he said the time had gone by when two Engineers

were needed; and, in his opinion, instead of the competition between them having been as to who should do best, it had been a competition as to who should squander most.

Mr. M. DAVIS denied that it had been the custom and an understood thing, as the Chairman of the Gas Committee had stated, that the Committee should make the advances and report to the Council. There was no such understanding. The Committee had taken upon themselves to do it; and if it had not been for the resolution passed at the last meeting of the Council, they would have known nothing of these large increases. The Committee ought not to be allowed to treat the Council in this way.

Mr. BRINSLEY said the increase which had been made in Mr. Smith's salary had been well canvassed outside the Council; and he contended that they had already been too good to their Secretary. He might be a good commercial man, but the man to whom they gave £1000 a year would be a very bad servant if he did not look after the bad debts; and with the monopoly the Corporation enjoyed, they ought to make very few, if any, bad debts.

Mr. JARVIS expressed surprise at the tone of the Chairman of the Committee in regard to the workmen and their holidays. At the last meeting of the Council, Mr. Bishop was persistent in refusing to give the holidays.

Mr. BISHOP: There was no persistency at all. I was from the first strongly inclined to grant what was asked.

Mr. JARVIS complained that large increases were readily made to the higher-paid officials; while the reasonable demands of the workmen were considered with great hesitation and reluctance.

Mr. THOMAS inquired whether the coke-wheelers at Adderley Street had received their long-promised holiday; and if not, why?

Mr. WALTER said the feeling of the people of Duddleston was very strong in respect to the increase of the salaries given to the highly-paid officials. He agreed that there should be a scale regulating the salaries, and that the salaries should be progressive; but when one officer's salary reached £1000 a year it was time to stop. He did not know whether it was competent for him to move an amendment without notice; but if it was, he would move that the salaries remain as they were before the increase. If he could not move it at that meeting, he would give notice to do so at the next.

Mr. ELI BLOOR thanked the Committee for the concession they had made to the carbonizers; observing that the holiday was thoroughly appreciated by all the men. With regard to the high salaries, he said, as a Trades Unionist, he had never voted against the raising of salaries. He had first of all ascertained what the ability of the official was; and he had generally found that he was worthy of the increase, and then he had invariably discovered that the salaries paid by the Corporation of Birmingham were lower than they were in other large towns. He thought, however, that the resolution proposed by Mr. Lowe—that in future the Committee should report all increases of salary of £50 and upwards—should be adopted. He could inform Mr. Thomas that the coke-wheelers were going to have their holiday.

Alderman POWELL WILLIAMS, M.P., thought what they had to ask the Committee was to give an explanation of the circumstances under which those repeated increases of salaries were not reported to the Council as they occurred. The Council had laid it down as a rule that no advance of salaries of £100 or upwards should be made without the circumstance being made known to the Council. That of Mr. Smith, however, appeared to have been raised from £1000 to £1250 without being reported to the Council at the time. This required an explanation.

Mr. MANTON believed it would be disastrous to the work of the Council if they hampered and cramped the extent of the Committee's operations. The fullest confidence should be placed in the Committee.

Alderman AVERY explained the powers given to the Committee, and pointed out that this body had not legally complied with the resolution of the Council appointing them, in not reporting the increase in the salaries. While he said this, he must also observe that, in the main, the Committee had managed admirably the great trust conferred upon them by the Council. It had been asked what had become of the profits made. From the reports of the Committee's proceedings, published from time to time, it appeared that they had accumulated a reserve fund and a sinking fund of very little, if any, less than £200,000. This they held as a guarantee against loss. Then they had paid the ratepayers, in direct contributions, sums of money varying from £20,000 to £27,000 a year in the twelve years they had been in possession of the gas undertaking, or something like a quarter of a million of money. Then in the reduction of the price of gas the consumers had had a benefit to the extent of certainly not less than £60,000 a year. He for one, was grateful to the Committee for what they had accomplished. They had not, however, literally complied with the directions given to them; and he hoped for the future they would make a point of stating to the Council what they had done and how they had done it. To take the Council into their confidence was a wise policy, and one that ought to be pursued.

The Mayor, in replying to the question as to what had become of the profits, said the Committee had, during the last twelve or thirteen years, contributed £305,000 to the improvement rate; they had accumulated about £254,000 as a sinking fund; and they had a reserve fund of more than £64,000—the total amount of saving thus being £319,000 in addition to the £305,000 paid to the improvement rate. What was the present condition of the gas undertaking? On the 31st of December last the capital embarked was £2,294,340. They paid for the gas undertaking £2,000,931; so that there was only an increase of about £294,000. If they deducted the amount of £319,000 which he had mentioned as saved, irrespective of what they had paid to the rates, they found that they owed £25,000 less than when they acquired the gas undertaking. They had now a plant 50 per cent. better than in 1876; they had bought 50 acres of land; they had paid a great portion of the expenses of the Art Gallery; they had enlarged the gas-works at Windsor Street; and they had completed the works at Saltley. He quite agreed that the increase of salaries should be reported; and that the Committee, in not reporting them, had simply been following a wrong precedent.

Mr. JACOBS contended that the price of gas in Birmingham was much higher than that charged in other large towns; and, in support of his contention, mentioned the price at Hull and Sheffield, where he said large dividends were paid to the shareholders of the Companies. In Birmingham they paid the paltry sum of £25,000 out of a capital of about £2,500,000. The Council certainly wanted a much stronger Gas Committee than the present one to manage the undertaking.

Mr. BOWKETT asked the amount of salary Mr. Smith received when he was first appointed Secretary of the Gas Department.

Mr. BISHOP said Mr. Smith commenced with a salary—in 1878—of £500. In 1879 it was increased to £600; in 1880, £700; in 1881, to £850; in 1882, to £1000; and in 1888, to £1250 a year. In answer to other questions, he said that if a week's holiday were allowed to each employee, &c., as well as each Bank Holiday, it would cost the Committee £1650 a year. As to Mr. Jacobs's remarks, the price of gas in Birmingham, he fearfully asserted, was as low, when all things were taken into consideration, as it was in any other town in the kingdom. They had been asked what they

had done with their money. He would remind the Council that £350,000. had gone into the pockets of the ratepayers; and the loss on the residuals between 1881 and last year was £58,000. Part of the economies had been absorbed in this way.

The motion was then agreed to.

SALFORD CORPORATION GAS SUPPLY.

RESIGNATION OF MR. HALLIGAN.—COST OF THE HUNTER PROSECUTION.—MR. ELLIS LEVER AND THE QUALITY OF SALFORD GAS.

At the Meeting of the Salford Town Council last Wednesday—the Mayor (Mr. Alderman A. L. Dickins) in the chair—various matters connected with the gas-works undertaking of the Corporation were brought forward.

The minutes of the Gas Committee, under date of the 17th ult., showed that Mr. J. F. Halligan, the Station Manager at the Regent Road Gas-Works, had resigned his position.

The minutes of the Finance Committee showed that, at a meeting held on the 21st ult., an extract was read from the proceedings of the Gas Committee, to which Committee the accounts incurred in the proceedings against Samuel Hunter and others by the Consultative Committee had been sent for payment, with an intimation that the Committee agreed to recommend the Council that any amount that might be hereafter received from Hunter should be placed to the credit of that Committee, and a resolution from the Gas Committee, in reply “that the accounts incurred by the Consultative Committee be remitted to the General Finance Committee, in accordance with the resolution of the Council.” The resolution of the Council was as follows:—“That the Consultative Committee be authorized to direct the General Finance Committee to pay the accounts referred to in the above-mentioned report, if found correct.” The accounts referred to (£927 Os. 6d., £263 13s. 8d., and £687 15s. 4d.) were submitted; and it was resolved to pay them. It was decided to place these amounts to a suspense account, pending the result of the civil proceedings against Hunter.

Mr. J. G. MANDLEY subsequently rose to move the following motion:—“That, having regard to the numerous complaints of the present quality of our gas, Mr. Ellis Lever be informed that the Corporation agree to the proposal made by him in his letter to the Manchester newspapers, dated the 26th ult., headed ‘Salford Gas;’ and that he be requested to name his nominees.”*

Alderman M’KERRON asked what was the proposal referred to. It had never been made to the Corporation officially.

Alderman KEEVNEY asked whether Mr. Mandley knew the decision the Gas Committee had come to that morning.

THE DEPUTY TOWN CLERK read the following resolution passed by the Gas Committee that morning:—“That in view of the motion of Mr. Mandley, based on the letter of Mr. Ellis Lever as published in the Manchester newspapers, this Committee are perfectly willing to afford Mr. Lever an opportunity of placing any statements which he may adduce before a Sub-Committee, consisting of the Mayor, the ex-Mayor, the Chairman and the Deputy-Chairman of this Committee, and Mr. Phillips; and if he can show a *prima facie* case, this Committee will ask the Council to institute a public inquiry into the matter.”

THE MAYOR said that if Mr. Lever made out a *prima facie* case, a public inquiry should be instituted, with an independent man as president.

MR. MANDLEY persisted in moving his motion. He said he did not intend to reflect upon the Gas Committee; he felt that they and the Manager were working under difficulties, because there must still be men at the works who had been accomplices of Hunter.

After some discussion, Mr. Mandley agreed to withdraw his motion, and accept that of the Committee; substituting the names of the Mayor, the ex-Mayor, the Chairman and Deputy-Chairman of the Committee, Mr. Sharrocks, and Mr. Phillips for those mentioned, and omitting the clause with respect to the public inquiry.

Alderman WALMSLEY said he was disinclined to grant the Committee; and he only agreed to it now because he believed it would result in Mr. Lever pronouncing his own condemnation. Mr. Lever had made similar applications before; and when opportunities had been given him, he had refused to make his charges.

THE MAYOR confirmed Mr. Walmsley’s statement. He said Mr. Lever had had several opportunities of making his allegations against the Gas Committee during the last six months. He had received telegrams from Mr. Lever asking for appointments; and when the appointments had been made, he had failed to keep them.

The motion for the appointment of the Committee was then put and carried.

THE RATING OF THE SOUTHAMPTON GAS-WORKS.

At the Meeting of the Southampton Guardians on the 27th ult.—the DEPUTY-PRESIDENT (Mr. H. Webb) in the chair—the Rating Committee reported that, having considered the question of the rating of the property of the Southampton Gas Company, referred to it by the Board, they had resolved to recommend that the gross estimated rental in the parish of St. Mary be increased from £8055 to £9438, and the rateable value from £4694 to £5500—an increase of £806 on the latter.

MR. BATES moved the adoption of the report. He said they were not entirely unanimous in Committee; but he was of opinion that they could well sustain the increase proposed; and they ought to do so in all fairness to other ratepayers in the town.

MR. WILLIAMS seconded the motion; saying the increase asked for was a very modest claim indeed.

MR. PURKISS proposed as an amendment that the assessment remain unaltered. He said he could plainly see that if they moved in the matter they would be drawn into litigation; and the last time they went to law on this question, it cost the town £4200. Now they were in a worse position; for while in 1875 the profits of the Company were £14,873, last year they were but £13,818—more than £1000 less.

MR. PARKER seconded the amendment, and pointed out that some members of the Board fought the Dock Company on the same lines; but the Act of Parliament directed them to rate on the profits, and although the Company had grown in every direction, unless the profits were proved to be greater, the Guardians would lose their case.

* The letter referred to was as follows:—“Sir,—Thirty-four years have elapsed since I commenced my commercial career in the borough of Salford. For nearly ten years I have been boycotted by the Salford Gas Committee because I ventured to tell them they were being defrauded. The numerous complaints appearing in the press as to the quality of the gas in Salford are fully justified; and if the Corporation will allow me to nominate two members of the Council, with power vested in them to nominate a third, I will undertake to show the Council within fourteen days how and to what extent the ratepayers are being defrauded. I have examined the affairs of the Salford Gas Committee; and I have no hesitation in saying that it would be next to impossible to find a town where the administration and the system of bookkeeping have been so entirely unsatisfactory. About the quality of the gas supplied, I would say that ‘You cannot make a silk purse out of a sow’s ear;’ neither can you have good and pure gas from coal and cannel which are notoriously bad, being charged with poisonous impurities.”

MR. PATSTONE supported the amendment; thinking it unwise to raise the assessment at the present time, especially as an electric lighting company was about to be established.

MR. BATCHELOR said that he should like further explanation. Everyone knew the vast increase of the Company’s works, including two large gas-holders, not rated, erected at a cost of £20,000. He should like to know, however, whether the profits had increased since the last appeal, or whether they were on works inside or outside the town. It seemed to him the Company could very well sustain an increased rating.

MR. EMANUEL said it might be perfectly true there was a tremendous increase; but this did not show profits.

Alderman ASLATT thought, as the Company would not object to be fairly rated, the Board might make an amicable arrangement with them.

THE DEPUTY-PRESIDENT was pleased that so many members had spoken in support of the amendment. It was thoroughly understood that these public companies were to be rated, to all intents and purposes, according to their profits. It was true there had been additions to the plant in the shape of gas-holders and a tram-line; but it should be known that these were carried out entirely from additional share capital, and not from profits. In 1877, when the appeal took place, the Recorder decided that the assessment should be £5800 for the borough. According to the professional valuer engaged by the Board, it was shown that the assessment should be on profits put at £14,873. Now, if they would take the Company’s balance-sheet for the last two years, they would find the profits were only £13,800. It might be asked how this came about; but a reduction of 1d. per 1000 cubic feet meant £1000 less profit. Since 1877 the price had been reduced from 4s. 6d. to 3s. per 1000 cubic feet. He had no hesitation in saying they would be doing a gross injustice by increasing the assessment, because he believed it would land them in further litigation.

MR. BATES, in reply, urged that though, on the occasion of the last appeal of the Company, the costs were heavy, they were repaid in a couple of years by the increased rating sustained.

On a division, the amendment was carried by 12 votes to 6.

Alderman ASLATT moved as a further amendment that a deputation wait upon the Company in order to arrive at some satisfactory mutual arrangement with regard to an increased rating. This was not seconded, and the original amendment was carried as a substantive resolution.

OLDHAM CORPORATION GAS SUPPLY.

THE PROPOSED EXTENSION OF THE HIGGINSHAW WORKS.

The Gas Engineer of the Oldham Corporation (Mr. J. Chadwick) has recently suggested to the Gas Committee the advisability of extending the storage capacity of the Higginshaw Gas-Works. He gave the following as his reasons:—“The present storage room at the Higginshaw Gas-Works is 1,600,000 cubic feet, and consists of four holders, each 100 feet diameter and 29 feet deep. The daily make of gas last winter was 1,800,000 cubic feet; the daily delivery of gas during the working days of last winter was 2,000,000 cubic feet. The daily delivery of gas in the winter of 1884 was 1,600,000 cubic feet. The daily increase of 1887 over 1884 is, therefore, 400,000 cubic feet. I think we may assume that the daily delivery of gas will have reached 2,500,000 feet in the winter of 1891. The gas-holder capacity should be equal (or thereabouts) to a maximum day’s delivery. It would take from two to three years to construct a new tank and holder. I have, therefore, to suggest to the Committee the desirability of making other provision in the storage capacity at the works, with the idea of utilizing the land to the best advantage. I propose to construct a gas-holder and tank considerably larger than those at present existing, which by comparison (and in connection with the large works into which those at Higginshaw are gradually developing) can only be called small ones. I have, therefore, prepared plans for a tank 200 feet in diameter and 30 feet deep—the holder to be on the telescopic principle, in two lifts. This would give an additional capacity of 1,600,000 cubic feet, or make the storage at Higginshaw double what it is at present. Doubtless this looks on the face of it a large increase to make at once; but when there is a constantly and continually increasing consumption of gas, when it is scarcely possible to go on with the whole apparatus exactly balanced for any length of time, and when it becomes necessary to increase certain portions of the apparatus, I think due regard should be paid to probable future requirements. Some members of the Committee will remember that considerable trouble and difficulty have been experienced with two of the present tanks at the Higginshaw works, in consequence of water having leaked out of them, and that during the repairs I found that the bottoms of the tanks were in close proximity to some old and disused coal workings, and that the water had leaked out there. In preparing the plans for the proposed tanks, I have, as I think, taken special precautions against any danger which might naturally be expected from previous experience. In the first place—and the nature of the ground favours this—I have kept the level of the proposed tank 12 feet higher than the existing tanks; and I propose to place a layer of concrete over the whole bed of the tank bottom and under the puddle. With these precautions, and others of a minor character, I have not the slightest doubt but that the tank can be constructed perfectly sound and watertight.”

THE PRICE OF GAS AT RAMSBOTTOM.—The Ramsbottom Local Board recently appointed a deputation to wait on the local Gas Company in reference to the price of gas for public and private lighting, and at the meeting of the Board yesterday week the Clerk reported the result of the interview. He said: “On behalf of the deputation I called the Directors’ attention to the following facts:—The Rossendale Union Gas Company charge private consumers 3s. 7d. per 1000 cubic feet, whereas the Ramsbottom Gas Company charge 3s. 11d. For public lighting the Rossendale Company charge the Bacup Corporation 3s. per 1000 cubic feet, and the Ramsbottom Gas Company charge your Board 3s. 6d. Your Board pay almost as much per lamp for gas alone as the Rawtenstall Local Board pay not only for gas (supplied by the Rossendale Union Gas Company) but also for wages, &c., for lighting and extinguishing the lamps, cleaning, repairs, painting, and putting the lamps in and taking them out and storing them at the termination of the lighting season. The Haslingden Union Gas Company charge private consumers 3s. 9d., and for public lighting 3s. 11d. per 1000 feet, and allow 5 per cent. discount to consumers if paid within 14 days; whereas the Ramsbottom Gas Company charge 3s. 11d. and 3s. 6d. respectively, and do not allow discount in any case. The Bury Corporation charge private consumers within the borough (except the newly added areas) 2s. per 1000 feet, and private consumers outside the borough and consumers within the newly added areas, 2s. 11d. per 1000 feet. Notwithstanding these facts, which clearly show how extraordinarily excessive the Ramsbottom Gas Company’s charges are when compared with those of other companies, Mr. Stead, on behalf of the Directors, said that his Company could not at present reduce their charges, and gave as a reason the fact that there was a considerable decrease in the price they now obtained for their residuals as compared with the price they obtained several years ago. The Directors promised that they would make a reduction as soon as they could see their way clear to do so.” No remarks were made upon the report.

THE GAS AND WATER ORDERS OF THE SESSION OF 1888.

The Board of Trade report on their proceedings under the Gas and Water Works Facilities Act, 1870, during the session of the present year has just been issued. It states that 24 applications were made to the Board for Orders, in which power was sought to raise £558,500 by shares, and £142,616 13s. 4d. by loans—a total of £701,116 13s. 4d. Of this sum, £217,500 of share and £56,750 of loan capital was for the purposes of gas undertakings; £186,000 of share and £47,166 13s. 4d. of loan capital for water undertakings; and £155,000 of share and £38,700 of loan capital was for the combined gas and water undertakings.

The applications for the Gas Orders were from the following places:—Chigwell, Loughton, and Woodford; Dursley; Great Berkhamstead; Hatfield; King's Lynn; Littlehampton; Oakham; Poulton-le-Fylde; Snodland; Swansea; and Workop. Six of these applications—viz., Dursley, Great Berkhamstead, Hatfield, Oakham, Poulton-le-Fylde, and Snodland—related to existing undertakings which, having no parliamentary powers, sought for authority to maintain and continue works already constructed, and to make and supply gas. The other five applications related to undertakings already possessing parliamentary authority, and sought for the following powers:—The Chigwell, Loughton, and Woodford Order, to extend the existing limits of supply and to raise additional capital; the King's Lynn and Littlehampton Orders, to construct additional works, to purchase more land, and to raise further capital; and the Swansea and Workop Orders, to raise additional capital. Objections were lodged against many of the Orders; but in no case was it deemed necessary to hold a local inquiry, and, with certain modifications and amendments, all the applications were granted.

The sliding scale of price and dividend was inserted in all Orders with the exception of the Swansea Order, the initial price per 1000 cubic feet being fixed as follows:—Chigwell, Loughton, and Woodford, 4s. 11d.; Dursley, 4s. 1d.; Great Berkhamstead, 4s. 7d.; Hatfield, 4s. 3d.; King's Lynn, 3s. 6d.; Littlehampton, 4s. 3d.; Oakham, 4s. 6d.; Poulton-le-Fylde, 5s. 10d.; Snodland, 4s.; Workop, 3s. 8d. In the case of the Swansea Order, the Board of Trade, after hearing and considering the objections raised by the Corporation, reduced the existing authorized maximum price (4s. in the borough and 5s. 6d. outside) to 3s. 9d. and 5s. respectively. The Corporation, however, renewed their opposition to the Order in the House of Commons, with the result that the maximum price was still further reduced by the Select Committee to 3s. 6d. in the borough; the maximum price of 5s. outside the borough remaining unaltered. In the Poulton-le-Fylde Order a clause was inserted by agreement, requiring the undertakers, under certain circumstances, to sell their undertaking to the Local Authority. The illuminating power was fixed at 15 candles in all Orders except the Poulton-le-Fylde Order, in which an illuminating power equal to 16 candles was prescribed. The Gas-Works Clauses Acts, 1847 and 1871, were incorporated where necessary; and the usual clauses as to sale of capital by auction or tender were inserted in all the Orders in which additional capital was authorized. The usual clauses as to limits of dividend and profit, pressure and mode of testing the gas, insurance and reserve funds, excess of profits, quantity of land to be taken by agreement, &c., were inserted in all Orders to which they were applicable. Two Bills to confirm the Orders were introduced into the House of Commons on the 7th of May. The Bill containing the Swansea Order was opposed in the House of Commons by the Corporation of Swansea, with the result that the maximum price to be charged for gas was reduced as previously stated, and a clause as to pressure of gas inserted. Neither Bill was opposed in the House of Lords; but, at the suggestion of the Chairman of Committees, the clause empowering the promoters to manufacture, purchase, and supply gas appliances and apparatus, &c., was modified so as to exclude "engines and machines for the production of motive power." Both Bills received the Royal Assent on the 24th of July.

The Water Orders were applied for in respect of the following places:—Barrow-upon-Soar and District; Hayward's Heath and District; Herne Bay; Kettering; Mansfield; Mid-Kent; Mid-Sussex; Wimborne Minster; Workop; Wotton Estate. Of these applications, five were promoted by new Companies, who sought power to construct works and to supply water in the following districts:—Barrow-upon-Soar and District; Hayward's Heath and District; Mid-Kent (parishes of Snodland, West Malling, &c.); Mid-Sussex (parishes of Hayward's Heath, Cuckfield, &c.); and Wimborne Minster. Of the remaining applications, four related to existing undertakings having parliamentary authority—viz., Herne Bay, Kettering, Mansfield, and Workop. In the Herne Bay and Workop Orders, power was sought to raise additional capital; in the Kettering Order, to construct additional works; and in the Mansfield Order, to extend the existing limits of supply and to raise additional capital. The remaining application—the Wotton Estate Order—related to an existing undertaking without parliamentary authority; and by it power was sought to maintain and continue existing works, to construct additional works, and to supply water. Orders were granted by the Board of Trade in eight out of the ten applications; but in the case of the Barrow-upon-Soar and District and the Hayward's Heath and District applications, the Board declined to grant Orders. In these two cases, the decision not to proceed was arrived at after consideration of the report of Major F. A. Marindin, R.E., C.M.G., who was appointed by the Board to hold a local inquiry in each case. With respect to Barrow-upon-Soar, the Local and Road Authorities withheld their consent to the application, and some of them actively opposed it. Major Marindin in his report stated that in his opinion sufficient reasons had not been given to justify the Board in dispensing with the consent of these authorities, and that he was unable to recommend that the Order should be granted. In the Hayward's Heath and District and Mid-Sussex Orders power was sought to supply water to the same area; and the Local and Road Authorities having consented to both applications, Major Marindin's inquiry resolved itself into one concerning the respective merits of the two undertakings. In his report he stated that, after hearing the arguments and evidence on both sides, he had come to the conclusion that the Mid-Sussex was the better scheme; and he accordingly recommended that this application should be granted. The Board of Trade, acting upon Major Marindin's recommendation, decided to refuse the Hayward's Heath and District application, and to grant the Mid-Sussex application, subject to certain modifications and amendments suggested in his report. In all Orders granting power to charge rates for the supply of water, the rateable value of the houses, as ascertained by the valuation list, was fixed as the basis on which the rates should be charged. In no case were the undertakers exempted from giving a constant supply. In the Mid-Kent Order it was provided that if, after three years, the Local Authority or 20 inhabitant householders of any parish should represent that the undertakers were not supplying the parish, and that other undertakers were prepared to do so, the Board of Trade might amend the limits of supply so as to exclude the whole or any part of such parish. In the Mid-Kent, Mid-Sussex, Wimborne Minster, and Wotton Estate Orders, the undertakers were authorized to supply water in bulk by agreement within and without the limits of supply subject to certain limitations. In the Wotton Estate Order, which was promoted by an individual proprietor, it was provided that no sale or assignment of the undertaking

should have effect until approved by the Board of Trade. In the Mid-Sussex Order a clause as to the purchase of the undertaking by the Local Authorities was inserted. Following the practice now adopted by Parliament, clauses were inserted in all Orders authorizing additional capital to secure the sale of such capital by auction or tender. Where necessary, the Water-Works Clauses Acts, 1847 and 1863, were incorporated, and the usual clauses as to regulations for preventing waste, misuse, or contamination of water, supply of water by measure, and the quantity of land to be taken by agreement, &c., were inserted. Two Bills to confirm these Orders were introduced into the House of Commons on April 23 and May 7 respectively. They passed through both Houses without opposition, and received the Royal Assent on the 24th of July.

There were three applications for Gas and Water Orders—viz., from the East Berks and West Oxford District, Sheringham, and Winchester. Two of these Orders were promoted by new Companies (East Berks and West Oxford District, and Sheringham), and sought power to construct gas-works and water-works, to make and supply gas, and to supply water. The third application was from the Winchester Water and Gas Company, who wished for power to purchase additional land, to raise further capital, to sell surplus lands, and to amend their Act of 1865. All three applications were granted. In the case of the East Berks and West Oxford District Order, many of the Local and Road Authorities were opposed to the application; and the Board of Trade, after consideration, decided to limit the operation of the Order to the parishes of Goring and Streatley, and to alter the title to the Goring and Streatley District Gas and Water Order. The Winchester Order was in the first instance opposed by the Corporation of Winchester; but upon the promoters agreeing to strike out certain of the provisions objected to, the Corporation withdrew their opposition, and the Board of Trade granted an Order authorizing the Company to raise additional capital. The sliding scale of price and dividend for the gas undertaking was inserted in the Goring and Streatley District and the Sheringham Orders; the initial price being fixed at 5s. per 1000 cubic feet in each case. The rates authorized by these Orders to be charged for water are to be based on the rateable value of the houses, as ascertained by the valuation list. In neither case were the undertakers exempted from giving a constant supply of water. The promoters of the Sheringham Order agreed to the insertion of a clause requiring them to supply and maintain a public tap at Sheringham, from which water for domestic purposes might be drawn free of charge. In the Goring and Streatley District Order and the Sheringham Order, the undertakers were authorized to supply water in bulk by agreement within and beyond the area of supply, subject to certain limitations. Where applicable, the Gas-Works Clauses Acts, 1847 and 1871, and the Water-Works Clauses Acts, 1847 and 1863, were incorporated; and the usual clauses as to limits of dividend, creation of an insurance and reserve fund, and excess of profits, regulations for preventing waste, misuse, or contamination of water, supply of water by measure, pressure and testing of gas, and quantity of land to be taken by agreement, &c., were inserted. A Bill to confirm these Orders was introduced into the House of Commons on the 7th of May. It passed through both Houses without opposition, and received the Royal Assent on the 24th of July.

Appended to the report as a tabular statement showing the number of Orders sanctioned by the Board of Trade from the passing of the Gas and Water Works Facilities Act, 1870, down to the present time. The total applications were 323; of these the Board granted 301, of which number 298 were confirmed by Parliament.

THE MASSACHUSETTS GAS COMPANIES AND THE MANUFACTURE OF WATER GAS.

A correspondent of the *American Gaslight Journal* gave, in the last issue of that publication to hand, an account of the proceedings before the Gas Commissioners of Massachusetts in connection with the petitions presented by certain Gas Companies of that State who are desirous of being authorized to manufacture water gas under the provisions of an Act passed last spring. The Companies concerned were the following:—Cottage City, Spencer and Miller's River, South Boston, Roxbury, Amesbury and Salisbury, and Brockton. The petition of the Spencer Company was first considered; their representative (Judge Hill) explaining that their desire to manufacture water gas was prompted mainly by the fact that it could be produced at less cost than coal gas. In this he was supported by the Company's Superintendent (Mr. E. Evans), who said it would cost \$24.75 to manufacture 50,000 cubic feet of coal gas in Spencer, whereas the cost of 100,000 cubic feet of water gas would be only \$27.124. The Spencer water gas he said contained 25 per cent. of carbonic oxide. He also stated that the men about the works were in good health, and that he had never heard of any accident occurring in the manufacture of water gas. Judge Hill's remarks also contained an interesting exposition of the success which had attended the reduced gas-rate; the rate at Spencer having been reduced to \$1 per 1000 cubic feet some months ago. In the summer of 1887 the Company placed 87 gas cookers, and last summer 105 others had been disposed of (Spencer contains probably 9000 inhabitants). The Company also rented out small heaters in the winter, which were returned during the summer season; and the number of heaters used in bed-rooms was between 25 and 30. The Company operated 9 miles of pipes, all of wrought iron. Only one break in the system had occurred, and that was the fracture of a T-piece, which permitted an escape of gas into a drain, whence it passed into the cellar of a house. The Amesbury and Salisbury Company's case was then taken up. The President (Mr. W. E. Biddle) testified that his Company employed the Granger process, and that, on a daily make ranging between 10,000 and 35,000 cubic feet, they charged \$2.50 to small and \$2 to large consumers. They did have one contract under which gas was sold to a manufacturing company at the rate of \$1.30 per 1000 feet. Mr. R. F. Briggs, a large gas consumer in the district, did not think that the gas sold by the Company was injurious to health, although he admitted that some trees along the line of gas-pipe had withered away. The President of the Commission (Mr. Commissioner Coffin) here read a communication, signed by 15 residents of Amesbury, setting forth that the manufacture of water gas was going on in that place without leave; that it was represented as detrimental to the public health; and that a number of trees had died along the line of the gas-pipes, owing, it was believed, to the passage near them of the poisonous gas. The petitioners asked the Commissioners to visit Amesbury for the purpose of making an investigation, and intimated that if the gas were shown to be injurious, they wished its manufacture to be stopped; if not, all cause for objection on their part ended. The Commissioners decided to hold an inquiry at Amesbury on Sept. 28, and then adjourned the general hearing to Oct. 9, when the petitions of the other Companies will be considered. The correspondent of our contemporary says the hearing was conducted in a thoroughly impartial manner, and reflected great credit on the good temper and apparent earnestness of the petitioners, while it also added new laurels to those already won by the Gas Commissioners. He adds: "Perhaps the wisdom of creating similar bodies in other States will soon become patent to those of the fraternity who, failing to lead, are very hard to convince that others could possibly open up a road over which all might travel in safety."

PETROLEUM FUEL.

[Extracts from a Paper by Mr. S. S. Leonard read at the recent National Electric Light Convention in New York.]

The use of petroleum is by no means of recent date; it was known to the ancient Greeks and Romans, being used by them for illuminating purposes, as they had no electric lights in that day. In fact, the word "petroleum" is of Latin derivation, meaning "rock oil." It has been, and is being, used for various purposes, from the sure cure of numerous diseases to the generating of steam for electric light stations. It is found in many parts of the globe, although there are but a few localities that are especially noted for its production. In America, New York, Pennsylvania, Ohio, and West Virginia produce the greater part of the supply. Although it was known to the early settlers of these States, very little importance was attached to its value.

To say that petroleum is a new fuel would hardly be correct; for petroleum has been used as such for a number of years. Experiments to determine its practicability as a fuel have been creating a great deal of attention from those interested in the matter for the last 20 years; and it is now occupying the minds of some of our ablest engineers and inventors. Quoting from a very able paper on this subject by Charles E. Ashcroft, which was published in the *Boston Journal of Commerce*, May 26, 1888, the author says that the calorific power of petroleum for the purpose of generating steam and the evaporation of water is several times greater than that of ordinary coal. The successful use of oil as a fuel has, however, been of very recent date, yet so rapidly has it grown in favour that to-day it is regarded as a strong competitor of coal for steam-generating purposes, or where heat and fire are wanted.

Its advantages over other fuels are many. In the first place, it is much easier handled; a steadier fire is easily maintained under your boilers, consequently the steam is kept at a more even pressure—a very important thing in the running of electric lights; there is no opening of furnace doors, allowing cold air to come in contact with the boilers and there are no impurities in the oil such as abound in coal. When you have done with it, by a turn of the wrist your fire is put out, and your ash-pits are as clean as they were before the fire was started. In less time than it takes to tell it, you can start the fire. It is only rivalled in handling by natural gas; and even then, unless we have all the modern appliances for the handling of this gas, it is far easier to manipulate.

Permit me to describe the arrangements for the handling and use of this oil put in under the supervision of the writer. The oil is received in tank cars, holding from 90 to 150 barrels each (42 gallons to a barrel). From these cars it is drawn off through a valve in the bottom of the car to a storage tank or tanks (there being two of them), holding about 300 barrels each. These are placed underground, so that the oil runs from the car into them by gravity. Care should be taken not to spill the oil or stir it up more than is necessary, as the odour from it is fully equal in strength to that of new-mown hay, if not quite so agreeable. To prevent the stirring up of the oil, the supply-pipes entering through the top of the tanks run nearly to the bottom, so that the tanks are practically filled from the bottom. In the top of each tank are man-holes and a vent-pipe. This latter is extended above the tanks a short distance. These tanks, which are boiler shaped, are placed end to end, with a space of about 8 feet between them. This gives room to get at the various pipes. They are joined together at the bottom by a pipe, which also connects with the supply-pipe running to the boiler-room. Then in the bottom of each is a drain-pipe, which will admit of cleaning them out whenever necessary. There is also a gauge-glass in the end of each, to show how much, if any, water is in them. There is also a gauge made by a copper float, which indicates the quantity of oil in each tank. In cold weather a steam coil is inserted in the tank car around the mouth of the valve to heat the oil so that it will flow readily; for when the thermometer is in the vicinity of 30° or 40° below, the oil is apt to be a little thick. Care should be taken not to heat the oil too much, for when hot it generates considerable gas, which is not only very odorous, but is really the cream of the fuel. I think it an advantage to have the storage tanks underground; there being less danger from them in case of fire, and during the winter the oil is less likely to chill. An open light should never be used near them, although the oil itself is really hard to ignite unless heated to a certain degree; still there is apt to be more or less gas around; which is explosive if brought in contact with fire. The supply-pipes to the furnaces are provided with a valve where they enter each tank, also one in the fire-room. This pipe, a 2½-inch one, is enlarged to a 6-inch, for about 4 feet, and in this 6-inch pipe a small steam-pipe is inserted. With this, the oil is heated from 130° to 140°. This lightens it so that it burns more readily, or, I should say, is turned into gas.

We now come to the burners, which are also fed by gravity, as the storage tanks, although underground, are still higher than the furnaces. One might suppose that, owing to the recent introduction of petroleum as a fuel, some difficulty might be experienced in obtaining a burner; but they are as numerous as electric light systems, and like them in another respect—each man's is the best. Our experience has been that the more simple the burner the better the result. One that thoroughly vaporizes the oil before burning it, is, we think, preferable to one that burns the oil. In the former there cannot possibly be any waste. In furnaces where we have been using this kind of burner, the bricks are as clean as they were the day they were put in. Steam and hot air are the other ingredients used in connection with the oil; and an abundant supply of the latter, we have found, adds very much to the efficiency of the fire.

Regarding the proper settings, circumstances will determine this to a certain extent. There is no doubt that a hotter fire can be obtained from oil than from coal or wood; and when the oil is properly used, the smoke nuisance question—which has been agitating the minds of the people of some of our large cities—is solved, for there is not a particle of smoke to be seen issuing from the stack, not even when everything is running full blast.

A word as to its danger. When properly put in and handled with ordinary care, or when good common sense is used in the employment of this oil, I do not see why it should be any more apt to cause trouble than coal, although the insurance companies insist on higher rates when used. I think it more from ignorance of the subject than from their being any more danger. At the same time, I am willing to admit that it could be put in and used in such a way as to greatly increase the danger of fire.

As to its economy over coal, I have already mentioned that there was a saving of from 20 to 25 per cent. on the cost of fuel, and from 40 to 50 per cent. in labour. From tests recently made by us, the following figures were obtained:—111.34-horse power, running six hours, used 250 gallons of oil, costing \$5.50, or at the rate of 70c. per 100-horse power per hour; 104.8-horse power, running six hours, used 346.1 lbs. of coal, costing \$5.45, or at the rate of 86c. per 100-horse power per hour. Another test gave the following figures:—96.45-horse power, running eight hours, used 401.47 lbs. of coal, costing \$6.32, or 80c. per 100-horse power per hour; 115.64-horse power, running seven hours, used 233 gallons of oil, costing \$5.05, or 62c. per 100-horse power per hour. On the above figures, oil is from 17 to 32 per cent. cheaper than coal. The highest evaporation made with oil was 14.8 lbs. of water per pound of oil with feed water at

103°, and with coal 5.38 lbs. of water per pound of coal, feed water at 103°. The coal used was a good grade of Illinois lump, costing \$3.15 per ton, but which is usually worth \$3.25.

In the matter of labour, one man can easily attend from seven to ten 150-horse power boilers, and then have less to do than if he were firing one boiler with coal. After a week's run with oil, boiler flues are much cleaner than they would be from the use of bituminous coal for one night. There being no ashes, you are saved the expense of handling them, as well as the dirt; and the former is no small matter where some 20 tons of coals are being used every 24 hours. I might say that the above tests were made during a part of the day's run; and it is our opinion that a more favourable showing could be made with the oil where a larger number of boilers are in use. It seems to work better with a good fire than where a small fire is sufficient.

BIRMINGHAM CORPORATION WATER SUPPLY.

At the Meeting of the Birmingham Town Council last Tuesday—the Mayor (Mr. Alderman Pollack) presiding—the report of the Water Committee on the subject of the proposed new works, to which reference was made in the *JOURNAL* last week, was presented.

Sir J. MARTINEAU moved that confirmation should be given to a resolution of the Committee agreeing that a loan for £50,000 for various works should be raised, repayable in 30 years, according to the condition imposed by the Local Government Board. He explained that the Local Government Board, having heard an application for their sanction to a loan of £100,000, had consented to the Council borrowing £50,000, on the condition that the period of repayment should not be extended beyond 30 years. As the works on which the money was to be expended were principally mains, the Committee did not consider that the limitation was an unreasonable one; and therefore they had no difficulty in consenting to the condition.

The motion was carried.

Sir J. MARTINEAU then formally moved the adoption of the report. He referred to the expenditure of £1945 7s. 2d. in connection with the main between Whitacre and Plant's Brook beyond what had been expected; and said this was due to a larger portion of the main having been duplicated than had been intended. When the main was duplicated throughout, there would be £1945 worth less work to be done. The arrangements which the Committee had made with regard to the stamping of water-fittings for manufacturers, and for making a small charge for water supplied to builders when putting up new houses, had been carried out without any friction. The former arrangement should contribute to preventing waste from defective fittings, and the latter would produce a not inconsiderable item of income to the department. With regard to the loan for further works on capital account, he would only remind the Council that the Committee reported fully in February last concerning works they proposed to carry out during the next five years. Under the Water Act of 1875, the Committee had power to borrow £150,000, and a further sum of £100,000 with the consent of the Local Government Board, but not without; while under their Act of 1879, they had power to borrow sums amounting to £300,000. In February last both the £150,000 and the £300,000 were exhausted; and so there remained only the £100,000, for which they had to ask the consent of the Local Government Board. They believed they would have obtained permission for the whole sum at once; but this was not the view of the Local Government Board. The latter thought they were to sanction every item from time to time; but as this would have been a very troublesome procedure, communications were made, with the result that the Board consented to give a general sanction for half the amount. The Committee stated in February that they did not intend to incur any of the proposed expenditure during the present year, except for the laying of mains in the extension of their system. They had carried out this policy, and were still adhering to it in the works now proposed to be entered upon for the extension of the water-mains to Acock's Green and Solihull—an extension which he believed would prove a remunerative one. As to the provision of fresh sources of supply, the Committee had the matter under consideration, but were not yet prepared to report.

Mr. SHAMMON seconded the motion, which, after a short discussion, was adopted.

PLYMOUTH CORPORATION WATER SUPPLY.

DIFFICULTIES WITH THE PROPOSED RESERVOIR.

A Special Meeting of the Plymouth Town Council was held last Wednesday—the Mayor (Mr. Alderman H. J. Waring) in the chair—to consider a report from the Water Committee, submitting a joint report from Mr. T. Hawksley and Professor Etheridge on the result of their examination of the site of the proposed storage reservoir at the Head Weir and land adjacent thereto, and to take such action thereon as the Council might deem necessary or expedient.

In the course of their report the above-named gentlemen say: "We find that the geological conditions of the ground on the line near the Head Weir, authorized by Parliament, are such as to almost, if not quite, preclude the idea of making a safe and sound water-tight embankment in that position. The valley, both in its bottom and sides, is filled to a great depth with a superstratum of granite debris of the character of a coarse sand, pervious to water, and possessing no retentive characters; whilst the substratum of rock upon which the debris reposes has not been reached in several instances, although the borings have been carried down to a depth of 80 and even 90 feet below the surface. The making of an embankment in this situation, and under these circumstances, would, in our opinion, be not only a precarious operation, but would also involve so many difficulties and such large expenses that we feel compelled to advise you not to make the attempt, but rather to seek such amended parliamentary powers as may appear to you advisable. We have caused trials to be made in several parts of the valley to the south of the parliamentary line, with only such partial success as will not justify us in making any recommendation for your consideration, except as follows:—Guided to some extent by the surface indications, we have had nearly 20 pits and borings put down in a line running almost due west from the Longstone Farmhouse; and from these investigations we are led to infer that an embankment may be constructed in this position with fewer difficulties, and at a smaller cost, than at any other available part of the valley situate between the Head Weir and Sheepstor Bridge. Difficulties of a formidable character still, however, remain, as named above, and can only be overcome by the exercise of more than ordinary care, energy, and skill. On the question of cost we are not at present able to offer a very definite opinion, because of the uncertainties to which we have referred; but we incline to the opinion that the undertaking may be well executed for less than £120,000, including the expense of works of construction and outlays to be incurred for the purchase of lands and buildings, and for other charges and compensation. In our opinion the line lastly described is the best the valley of the Meavy affords within the area to which our attention has been called."

Mr. MOON said that the Water Committee had unanimously adopted the

joint report which had been presented, and had decided to ask the Council for instructions. He detailed at length the onerous labours in which the Committee had been engaged since March last, and explained the position in which they were placed. Referring to the difficulties connected with the site of the proposed reservoir, he said that, at the meeting of the Committee on the 4th ult., Professor Etheridge stated that in no part of Great Britain were they so great as in their case—they were, in fact, almost insurmountable. He added that the care which had been exercised by all concerned was beyond all praise; and the money had been spent in the most economical manner. At the same meeting Mr. Hawksley expressed his entire concurrence in Professor Etheridge's observations, and confirmed every statement he had made. On Sept. 28, Messrs. Hawksley and Etheridge presented the report now before the Council. Since the report had been printed, he had received several letters from Mr. Hawksley, in the course of which he explained that his estimate included a sum for 40 acres of additional land necessary to be purchased if the Head Weir reservoir was to be made. He also wrote as follows:—I understand it to be the wish of the Council and of the town, too, that the reservoir should be made so as to collect and deliver its water into the leat in the vicinity of Head Weir, or above Sheepstor Bridge. If some new situation is to be sought for and adopted, then, at least, 100 acres will be wanted; and in that event what is to be done with Sir Massey Lopes and his present agreement? I do not see how delay will help the matter. The dilemma to which I have pointed will be exactly the same in another session as in the coming session, unless, indeed, it is made worse by Sir Massey in the meantime insisting on the payment of the great sum of £15,750. As to this, however, I do not presume to offer any opinion; but one point I should like to be clearly understood by the Council, and that is that your explorations have been most valuable in two ways. First, they have settled the question of the impracticability of the line insisted upon last year; and, secondly, they have demonstrated amongst all the lines the comparative economy of the line upon which Professor Etheridge and I have just reported." In closing his speech, Mr. Moon remarked that the opinion of a high geological expert was that the site they had selected was a unique one. However, a town's meeting on July 6, 1883, emphatically declared for the Head Weir site; and another meeting on Nov. 26, 1886, unanimously approved of parliamentary powers being applied for to obtain the site. The Committee had been loyal to the inhabitants in the perseverance with which they had prosecuted their labours up to the present point. The result was before them; and if the Council and the inhabitants desired to incur the cost, by all means let it be incurred. If, on the other hand, it was desired to put forward the desirability of the Harter or of any other streams in the neighbourhood, then let the explorations be made; but they must bear in mind that they would lose one year of benefit and of future financial profit. He moved the adoption of the Committee's report, which embodied the report of the two experts.

Mr. WOOLLAND seconded the motion, and it was agreed to. Alderman HARRIS stated that at present the water revenue was estimated to produce £11,200 in round figures. The charges on this were, in the first place, about £3000 for maintenance and £800 for salaries. Then there was a debt of at least £40,000 at the present time, which at 4 per cent. was £1600. The reservoir put before them that day was estimated to cost £120,000. But estimates were exceeded; and looking at experience in all directions relative to water-works, it was doubtful whether it would be carried out for the money. Supposing it was; this would mean a charge of £4800 a year; and putting all the sources of expenditure together, they got a total of £10,200 on an income of £11,200—thus leaving a surplus revenue of but £1000 a year. The matter was so important that he did not think they should proceed further with it in the coming session of Parliament. He moved that they should not go on with the matter in the next session of Parliament, which would allow time for consideration, and perhaps the selection of another site.

Alderman FILLMAN seconded the motion, and expressed himself greatly disappointed that, after the statements again and again made in the Council Chamber that the reservoir was to cost £25,000, it was suggested that £120,000 should be spent upon it.

Mr. WOOLLAND remarked that the mover of the resolution had forgotten to tell them that there would be a very considerable increase in income when they had the new reservoir. If the Surveyor had been asked to test the valleys, he believed that the Harter site would have proved a most efficient and economical one. He proposed, as an amendment, that the Surveyor should receive instructions from the landowners to test any part of the moor which he considered necessary.

Mr. MORRIS seconded the amendment, because he thought it was the common-sense view of the situation.

Mr. LATIMER said it was his impression now, as it was last year, that they rushed into the application to Parliament for the Act much sooner than they should have done, and that they ought to have tested the Harter site before they agreed to pay so large a sum of money for the site they had chosen.

Mr. BELLAMY asked why, instead of wasting a considerable sum of money on a "roving commission," Mr. Woolland's resolution should not be modified, and instructions given that, under the direction of Mr. Hawksley, the Harter site should be examined, in order that it might be seen whether it was a fit and proper place for a reservoir. They certainly should commence with the Harter site before going farther. He proposed that the resolution should read that the Surveyor should make the necessary borings at Harter.

After some discussion, the resolution before the Council was submitted in the following form, and carried unanimously:—"That the Water Committee be instructed to test any part of the valleys that they may think desirable for the reservoir before going to Parliament."

Referring to the reservoir question last Thursday, the *Western Morning News* said:—"The position in which the town is placed is singularly unfortunate. It has acquired from Sir Massey Lopes, at a cost of about £16,000, land intended for a reservoir. It has obtained a Bill in Parliament enabling that land to be paid for and a reservoir constructed. Neither of these things has been done. Sir Massey, however, holds an undertaking from the town to pay him the sum agreed upon; and unfortunately there has been omitted from that agreement a clause, which existed in a prior agreement, to the effect that if the borings proved unsatisfactory the town might be released from its bargain on paying a fine of £1000. This reasonable and necessary stipulation, it appears, ceased to have force when the Bill received the Royal Assent. It will be interesting to learn who is responsible for this omission. But as facts now stand the town is completely at the mercy of Sir Massey Lopes. It has agreed to buy of him for £16,000 land which it cannot utilize without buying 40 acres more at an unknown price; and if the present site be altogether abandoned, and another be purchased, still there will be further land required. There is, however, this clue to the cost of the land at Harter—that Sir Massey Lopes definitely promised to sell it to the town for £5000. No one can imagine that he would go back from that, especially if he has received also a very large sum for the Head Weir site, which has proved useless. Being in this dilemma, the Town Council wisely decided yesterday

to 'hark back.' By reason of a perfectly unique geological formation, so Professor Etheridge and Mr. Hawksley say, modest local talent notwithstanding—an embankment can be constructed at the Head Weir only at a prodigious outlay of perfectly uncertain amount, although, as a guess, £120,000 is named. Mr. Hawksley has from the first under-estimated the value of money in the West. It is true that an adequate supply of pure water is so priceless a boon that if the 100,000 inhabitants of Plymouth and its neighbourhood were compelled to pay £1 or £2 a head in order to obtain it, they would be wise to do so. But if they are not so compelled—if they can get such a supply, as we have hitherto been told, for £60,000—Plymouthians do not want to pay double or treble this sum simply to be able to boast of large figures, or to give large percentages to engineers. There are plenty of better ways in which, for town improvements, money so saved can be spent; and the water revenue has proved too valuable a possession in times past to admit of its being lightly absorbed by water-works expenditure. So the Water Committee are now instructed to search anew for a site for a reservoir of sufficient but not exaggerated size, which can be made at a reasonable cost; and, until the facts have been fully elicited, application for parliamentary powers is deferred. Obviously, this is the best that can be done under the circumstances."

THE METROPOLITAN BOARD OF WORKS AND THE SEWAGE PURIFICATION OF THE THAMES.

THE CHEMICAL EXPERIMENTS.

In the JOURNAL a short time since, various references were made, in our articles on "Water and Sanitary Affairs," to the reports presented to the Metropolitan Board of Works by Sir H. Roscoe on the treatment of the sewage of the Metropolis. It may not be uninteresting, in connection therewith, to trace the steps which led up to the appointment of the above-named distinguished Chemist, from the information contained in the last annual report of the Board.

The report states that the disposal or treatment of the sewage of the Metropolis in such a manner as effectually to prevent its polluting the River Thames, has probably been the most important of the many subjects which have occupied the Board's attention during the past few years. In 1882, in consequence of complaints made to the Secretary of State for the Home Department by the City Corporation, in its capacity of Sanitary Authority of the Port of London, and by the inhabitants and local authorities of Erith, a Royal Commission was appointed to inquire into, and report upon the system under which the London sewage was discharged into the Thames; also to ascertain whether or not any evil effects resulted from it, and in that case what measures could be applied for remedying or preventing the same. The Royal Commissioners made two reports—one in January and the other in November, 1884. In their first report they came to the conclusion that at certain seasons evil effects did result from the discharge into the river of sewage in its crude state; such evil effects showing themselves in a foul state of the water, and in an accumulation of mud, causing offensive smells and other inconvenience. In their second report they expressed the opinion that it was neither necessary nor justifiable to discharge the sewage in its crude state into any part of the Thames; that some process of deposition or precipitation should be used to separate the solid from the liquid portions of the sewage, and that such process might be conveniently and speedily applied at the two present main outfalls; that the liquid portion of the sewage remaining after precipitation of the solids might, as a preliminary and temporary measure, be suffered to escape into the river, but that it would not be sufficiently free from noxious matters to allow of its being so discharged permanently; and that the separated liquid would require further purification, which in the Commissioners' opinion, according to the then state of knowledge, could only be done effectually by the application of the liquid to land. If suitable land in sufficient quantity and at reasonable cost could not be procured near the present outfalls, the Commissioners recommended that the sewer liquid, after separation from the solids, should be carried down to a lower point of the river, at least as low as Hole Haven, and there be discharged.

The Board gave the most careful attention to the Commissioners' reports and to the evidence upon which their conclusions were arrived at. Notwithstanding, however, the great weight to be attached to the opinions and recommendations of the Commissioners, the Board felt that it could not divest itself of the statutory responsibility which devolved upon it of devising a scheme of dealing with the sewage which should be at the same time thoroughly effective, and yet not necessarily burdensome to the ratepayers upon whom the expense would fall. Some of the Commissioners' conclusions received the ready assent of the Board. For instance, the inquiry had made it tolerably clear that, at certain seasons when heat and drought prevailed, the discharge into the river of sewage in its crude state was to some extent productive of nuisance. The discharge of crude sewage could not be said to be absolutely necessary; and, this being so, the Board were of opinion that it would not be justifiable to allow it to continue. Accordingly, the Board determined to apply, as soon as practicable, some process of deposition or precipitation to separate the solid from the liquid portion of the sewage, and to allow only the fluid which remained after precipitation to pass into the river. Careful experiments made, first with small and afterwards with larger quantities of sewage, showed clearly that chemical precipitation of the matter held in suspension could be satisfactorily effected by adding to the sewage certain proportions of lime and protosulphate of iron, and then allowing it to remain for an hour or two in settling-tanks. The Board submitted the results of the process to four independent Chemists of the highest standing—viz., Sir Frederick Abel, Dr. Odling, Dr. A. W. Williamson, and Dr. A. Dupré—one of whom (Dr. Williamson) was a member of the Royal Commission above referred to. These gentlemen advised that the method of precipitation adopted was a good one, and that it produced a fairly clear liquid, but that it left a sufficiently unpleasant smell to prohibit the effluent water being discharged into the river during warm weather at all states of the tide. It appeared, in fact, that the clarification of the sewage would not be sufficient to ensure complete immunity from smell arising from secondary fermentation and a fresh development of offensive gases in hot weather. Such immunity, however, it was deemed necessary to attain.

The Royal Commissioners seem to have been of opinion that the only effectual way of attaining it was, after precipitation of the solid matter, to further purify the liquid by a process of filtration through earth; and they advised that such a process of filtration should be adopted if it was decided to discharge the sewage effluent into the Thames in the vicinity of the present outfalls. The acquisition of sufficient land, however, in the neighbourhood of Barking and Crossness to enable the vast quantity of London sewage to be effectually filtered through the soil was found to be attended with such great difficulty, to say nothing of cost, that the Board conceived it to be its duty to endeavour, under competent advice, to find some other method sufficiently effective to obviate the necessity of earth filtration. What was required seemed to be an oxidizing agent which would not only effect the immediate destruction of any offensive odour still remaining after chemical precipitation, but would at the same

time prevent the development of noxious gases. It was found that permanganic acid was effectual in accomplishing both these objects.

The Board were extremely anxious that there should be no mistake in the conclusion arrived at upon this important point, as upon it would mainly depend the determination of the course to be taken. The Board accordingly again sought the opinion of the four eminent Chemists who had already advised upon the method of precipitation. They all, after careful observation of the experiments made, gave it as their opinion that, if the liquid resulting from precipitation with lime and protosulphate of iron were subsequently treated with manganate of soda and sulphuric acid, it would be deodorized and purified to such an extent as to render its discharge into the river unobjectionable at all states of the tide. With this authoritative opinion before it, the Board felt that the filtration difficulty might be regarded as overcome, and that it might safely be concluded that the adoption of the process of precipitation, with the further resort to permanganic acid in hot weather, as proposed, would effectually render the discharge of the sewage into the river innoxious and inoffensive all through the year.

This conclusion arrived at, the Board proceeded at once to act upon it, and ordered plans to be got ready for the works necessary to enable the process to be brought into operation. The plans for the works at Barking, the site of the outfall on the north side of the Thames, were first prepared; and in January, 1887, a tender was accepted for the execution of the works for the sum of £406,000. The undertaking comprises the construction of sludge settling and precipitation channels, sewer outlets, iron-water and liming station, engine and boiler houses, two chimney-shafts, a superintendent's house, twelve cottages for workmen, and a pier and jetty. [Some particulars in regard to these works will be found below.]

Whilst the permanent works at Barking have been in progress, experimental operations have been going on at Crossness. The total quantity of sewage treated during the past year has been a little more than 2000 million gallons. The wet sludge obtained therefrom amounted to 62,000 tons, which, on further settlement in the subsiding-tanks, was reduced to 41,000 tons. Of this quantity 39,556 tons were pressed into 14,401 tons of sewage sludge cake; the remaining 1444 tons being treated for experiments in various ways. About 10,985 tons of the cake were delivered last year into trucks at the Abbey Wood Station of the South-Eastern Railway, or into vessels alongside the Board's wharf at Crossness, free of charge, to farmers and others who applied for it for experimental use in agriculture.

As regards the permanent method of disposing of the sludge, it may be mentioned that the Royal Commissioners suggested that it could be applied to the raising of low-lying lands, or burned, or dug into land, or carried away to sea. The Board, having considered with care these various suggestions, came to the conclusion that the only practicable course, in the case of the Metropolis, was to carry the material away and cast it into the sea, unless it should fortunately turn out that the sludge could be applied with advantage for agricultural purposes. Every facility has been, and will continue to be afforded to persons willing to try the use of the sludge for agricultural purposes. As, however, the Board felt that, even in the most favourable circumstances, considerable time must elapse before the merits of the sewage sludge as a manure could be so widely recognized that farmers would be found ready to take the whole of the supply off the Board's hands, and as it was necessary to provide for its removal at once, the Board gave directions for a vessel to be specially constructed for the purpose of carrying the sludge out to sea, and there discharging it.

The vessel was built at a cost, including fittings, of £16,952 10s. It was launched on the 25th of May last year, and arrived in the Thames, off Erith, on the 29th of June following. The vessel will carry the sludge at such a level that it will have a sufficient head of discharge when the vessel is loaded; the head being maintained by the rising of the lightened vessel as the sludge flows out.

During the long-continued hot and dry weather of the past summer, it was found necessary (as in the previous year) to deodorize the sewage of the two main outfalls, before allowing it to pass into the river. The Board, thinking it desirable to obtain the opinion of some leading Chemist who had not previously been consulted on the subject, had recourse to Sir Henry Roscoe; and, under his advice, chloride of lime and subsequently manganate of soda with sulphuric acid were used at the outfalls. During the first two months—viz., from the 2nd of July to the 27th of August—chloride of lime was employed; 980 tons being used at Crossness and 1231 tons at Barking. From the 27th of August to the 5th of October, when the deodorizing operations ceased, manganate of soda in conjunction with sulphuric acid (making permanganate of soda) was the agent employed; 870 tons of manganate of soda and 388 tons of sulphuric acid having been used at Crossness, and 1208 tons of manganate of soda and 368 tons of sulphuric acid at Barking. In addition to the foregoing, there were also used for the purpose of experiments in the outfall sewer at Deptford, on the 4th and 5th of August, 109 tons of sulphuric acid and 95½ tons of manganate of soda. The total quantity of chemicals used during the 95 days the deodorizing operations were in progress was 2211 tons of chloride of lime, 2173 tons of manganate of soda, and 885 tons of sulphuric acid; and the total cost of the same was £42,467 12s. 1d.

THE NEW PRECIPITATION WORKS AT BARKING.

At the present time the whole of the sewage of the Metropolis north of the Thames is conveyed to Barking Creek by three culverts, each 9 feet high by 9 feet wide; and is, in the first instance, delivered into a covered reservoir divided into 4 compartments, and altogether extending over an area of 9 acres. The sewage is stored in this reservoir during eight hours of each tide, and discharged into the river at high water at the top of the ebb. This reservoir is situate on the east side of the sewer, and immediately adjacent to the river bank.

The new works consist of covered precipitation-tanks adjacent to this reservoir on its north side, and occupying the ground between the Outfall Sewer and Barking Creek, an area of between 10 and 11 acres. There will be 13 of such tanks, each 31 feet 6 inches wide and averaging about 1000 feet long. Communications will be made between the Outfall Sewer and each of these tanks, each fitted with two penstocks, so that communication may be opened or shut off at pleasure. The sewage will be admitted into each of the tanks in succession, and after being allowed to remain quiescent for a sufficient time to admit of the deposit of the solids in the sewage, the precipitation of which will be expedited by the admixture of 3·7 grains of lime and 1 grain of proto-sulphate of iron per gallon, the effluent will be run off over a weir which will fall as the water in the tank lowers, so that the top film of the effluent only will be taken off, and the tank emptied gradually so as to prevent any disturbance of the solids by the operation.

The effluent after flowing over the weirs (of which there will be ten in each tank), will pass into culverts carried transversely under the tanks and extended, some into the compartment of the existing reservoir, and some into a chamber under the Outfall Sewer through which, at present, the sewage is discharged into the river from the existing reservoirs.

When the level of the tide will admit, the effluent will be discharged through this chamber direct into the river; but when the water in the river is too high to admit of this the effluent will be conveyed by the other culverts into the several compartments of the present reservoir, and stored there until the level of the water in the river will admit of its discharge.

When each compartment is emptied of the effluent, the sludge, which will be in a semi-liquid state, will be discharged through culverts passing under the Outfall Sewers into a collecting culvert, from which it will be conveyed by pipes into a receiving well or sump, and pumped into a series of 12 tanks placed side by side and situate between the Outfall Sewer and the river. These tanks will each be 20 feet wide and 140 feet long, will cover an area of over an acre and a half, and, like the precipitation-tanks, will be covered so as to prevent nuisance.

The sludge will be allowed to remain quiescent in them so as to allow of a further precipitation, and the effluent water will be discharged over weirs into a culvert which will convey it into a store under the tanks, from whence it will be lifted and discharged through pipes to the liming station, there to be mixed with lime which is used for precipitation. The settled sludge remaining after this further precipitation will be discharged through culverts into a sludge store situate under the tanks, and will be lifted thence and conveyed by pipes along a jetty, and to a landing stage to be erected in the river, and there discharged into ships which will convey the sludge to sea. In the event of the ships being detained by stress of weather there is a further store for sludge at a lower level extending under the whole of the area occupied by the upper stores.

On the north side of these sludge tanks will be erected engine and boiler houses and workshops in connection, to contain engines and machinery for lifting the sludge into the tanks, and the settled sludge into the ships, as well as for pumping the sludge effluent to the liming station. The lime for assisting the precipitation of the solids of the sewage is introduced into the Outfall Sewers at a point about 700 yards and the protosulphate of iron about 530 yards above the precipitation channels.

The liming station will comprise a lime store, floors for slaking the lime, and six tanks for mixing the slaked lime with the effluent water from the sludge settling-tanks or with sewage taken direct from the Outfall Sewers; an elevated lime-water tank or reservoir built above the lime store, and into which the lime-water will be lifted by pumps, for which machinery and the requisite engine and boiler houses will be erected adjacent to the lime stores. From this elevated tank the lime water will be conveyed to and injected into the sewage passing along the Outfall Sewers, through cast-iron injectors placed in the sewers.

There will be means of turning the lime-water into any one of the three lines of sewers and of regulating the supply by means of sluice-valves fitted to the pipes leading to the injectors. The injectors consist of cast-iron chambers 4 feet 6 inches in length, 6 inches wide, and 6 feet in height, fitted with a number of nozzles, through which the lime-water will be injected and mixed with the volume of the sewage as it flows past.

The iron-water station comprises timber shed for storing the protosulphate of iron, a mixing-shed in which the iron will be crushed and mixed with water, an engine-shed to contain engines and machinery for crushing the iron and mixing it with water, as well as for raising water for boilers and into mixing tanks. The iron-water will be conveyed by stoneware pipes, carried underground and along the top of the Outfall Sewer into a service-tank, from which it will be carried by pipes into each of the three Outfall Sewers, and injected into the sewage through perforations in a pipe fixed vertically in each of the sewers. As with the lime water, there will be appliances for regulating the supply of iron water to each of the sewers, to meet the varying requirements of the discharge.

There will be a large settling-pond, covering an area of 1½ acres, situate near the river, divided into six compartments, each 60 feet by 60 feet, and about 7 feet deep, into which water will be received from the river and allowed to settle; the clear water being afterwards filtered and used for the supply of the several boilers, for slaking the lime, and for mixing with the proto-sulphate of iron.

The jetty, which will extend 576 feet into the river from the present river bank, will be 15 feet wide, and will be a timber structure supported upon piles. At the river end of the jetty will be a timber landing stage 300 feet in length and 20 feet wide.

The iron pipes for conveying the sludge to the ships will be carried under the platform, and will be furnished at the end with a delivery pipe, socketed to admit of a vertical movement, so as to discharge the sludge into the ship at varying levels of the tide. A tramway will be laid along the full length of the jetty connecting it with the whole of the works.

The contract for the works includes the erection of 12 cottages and a residence for the superintendent, and the diversion of the Old Galleons sluice and ditch, which is one of the main sewers under the jurisdiction of the Essex Commissioners of Sewers.

There will be a large quantity of surplus earth from the excavations which will be used in forming the banks for the tramways, and in raising the general level of the ground, which is now 6 or 7 feet below the level of Trinity high water.

The works extend over an area of about 50 acres, the quantity of sewage to be dealt with will amount to about 90,000,000 gallons per day, and the quantity of lime to be used in precipitation to 23 tons per day.

Two contracts have been entered into for the execution of the works—one (as stated above) with Messrs. Mowlem and Co., for the general work, for £406,000; and the other with the Glenfield Company, of Kilmarnock, for engines and machinery, for £42,567.

REDUCTIONS IN PRICE.—The Directors of the *Newcastle and Gateshead Gas Company* have agreed to reduce the price of gas in Benton and Forest Hall from 3s. to 2s. 9d. per 1000 cubic feet, less the usual discount for prompt payment. The reduction will take effect on the 1st of January next. —At *Colnbrook*, where the gas-works have just passed out of the hands of the Colnbrook Gas Company (who had been in possession since June last) into those of a local firm of coal and corn merchants, the price of gas has been reduced by 6d. per 1000 cubic feet.

DARLINGTON CORPORATION GAS AND WATER SUPPLY.—At the meeting of the Darlington Town Council last Thursday, Mr. Manson moved the adoption of the half-yearly report of the Gas Committee. The profit, after paying interest, for the six months ending June 30 last was £2276. Taking off liquidation, £1582, there was left a profit of £694. There had been an extraordinary expenditure for plant, &c., of £277, and 4d. per 1000 feet had in two years been taken off the price of gas, which was equal to £1000 for the half year. The report was adopted, as was the Water Committee's report and accounts, which showed a revenue of £5038—an increase of £128. There was a profit of £177, after paying liquidation. The Gas Committee have just accepted the tenders for next year's coal—6000 tons of Binchester screened coal, at 8s. 3d. per ton; and 4000 tons of Kelloe treble nuts, at 8s. These figures show the prices now asked for coal delivered to gas-works only about a dozen miles from the edge of the Durham coal-field.

NOTES FROM SCOTLAND.
(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, *Saturday.*

Mr. Smith Clark, of Edinburgh, has been again illustrating the marvelous fertility of his mind, and at the same time how far wrong it is possible for a really able man to go when his reasoning is not founded on a correct basis. On Wednesday night last he addressed his constituents—a preliminary to the ensuing Municipal elections; and, in the course of his speech, referred to the Edinburgh gas transfer in terms so extraordinary, that I am afraid I must reproduce them somewhat fully in order that I may be able to treat of the fallacies which underlie his remarks. "He observed," he said, "that one of majority of the Council, in speaking to his Ward Committee about a week ago, said, 'he thought the gas purchase would turn out a very good thing for the city after all.' Why was it, seeing the published statements for the last year showed a net profit of £9000, that he left this as a matter of opinion? He thought he could tell them. It was because that gentleman knew that the Leith Company's accounts before they were submitted to Mr. Lass had all been remodelled. The fact was that owing to—should he call it the folly of their representative, in this transaction?—the two Companies were left to spend or not to spend as they chose upon the all-important matters of repairs and depreciation. They, of course, chose to spend as little as they possibly could. What the Edinburgh Company spent they had no precise means of knowing; but they knew that the Leith Company during the last year expended £4000 only under these heads. He inferred that the Edinburgh Company probably spent less; but he would assume that it spent as much. If the two Companies had charged revenue for repairs, depreciation, &c., at the same rate as the Glasgow Gas Corporation did per 1000 cubic feet of gas sold, they would have debited it with a sum of £50,000 instead of £8000. In this way the £63,000 of apparent profit would have been reduced to £21,000, for which they were paying £54,000 per annum—a deficit against the city of £33,000. This deficit, fortunately for them and him, would probably be reduced in the current year in consequence of the somewhat cheaper price of material; but he told them that if this question of repairs and depreciation were based on the same fair and equitable footing that it was based in Glasgow, they would escape from the consequences of their bargain with remarkable cheapness if they got off with an addition of about 2d. per £1 on the taxation. Unless circumstances arose which at present they had no reason to anticipate, the gas purchase would form a financial blight upon the progress of the city, he feared for the next quarter of a century."

Mr. Smith Clark is wrong on the following points:—(1) He did not explain when speaking of the remodeling of the Leith Company's accounts, that this was done to bring them into the style prescribed by the Gas-Works Clauses Act, 1871. The Company did not work under that statute, having an Act of Parliament of their own, passed in 1840; and their accounts were kept in accordance with it. But when it came to a question of transferring the undertaking to the Corporation, they re-cast the accounts, in order to facilitate a comparison with accounts kept under the modern statute. The Company at the same time produced their own accounts; so that no prejudice could have been done to the purchasers. As a matter of fact, the surpluses are very much larger under the remodelled accounts than under the old form. (2) The Companies were not left to spend or not as they chose upon repairs. The Edinburgh Company were bound by their provisional agreement to keep their works "in good working order;" and the Leith Company, not having been settled with, would find it to be to their interest not to let the condition of their works down until a bargain was made. The Leith Company's expenditure of £4000 is only £200 below the expenditure of the previous year, when the question with them was not that of transfer but of fighting the Edinburgh Company, and when, consequently, there was no likelihood of their neglecting the maintenance of their works. (3) No comparison can be made between Edinburgh and Glasgow. On account of the state of the Glasgow works at the date of the transfer to the Corporation in 1869, a very large expenditure upon repairs has been necessary ever since. The capital of the Glasgow undertaking is more than three times that of both the Edinburgh and Leith undertakings; and its business is about double. Therefore, on the basis of capital, had the two places compared been on the same level as regards the condition of the works, the expenditure in Glasgow should be three times that of Edinburgh, and, on the basis of the amount of business done, twice that of Edinburgh. In Glasgow the expenditure was £39,000; in Edinburgh and Leith Mr. Smith Clark places it at £8000. Taking these figures, the outlay in Edinburgh and Leith should, on the basis of capital, have been one-third, or £13,000; and on the basis of business done, one-half, or £18,500. Of course, I dispute the comparison; but apart from that, there is sufficient to demolish Mr. Smith Clark's position in the fact that he contended for an expenditure of £50,000 for repairs and maintenance in Edinburgh and Leith, which would have been £11,000 higher than the amount spent in Glasgow. I need not pursue the subject further. Mr. Smith Clark is an alarmist whom it would be futile to try and convert. It is fortunate for the community that his malady is of so pronounced a type, because his statements are usually more forcible than wise, and so defeat their object. His attempt to scare the public over a prospective gas-rate of 2d. per £1 is, on the face of it, absurd in the extreme. No movement in that direction will be made, should it ever be necessary, until the Gas Commissioners have exhausted the more natural method of increasing their revenue—raising the price of gas.

The Perth Town Council, at their meeting last Monday, had before them a recommendation by a Committee to sell 1½ acres of land on the South Inch to the Gas Commissioners, to be used in connection with the extension of the gas-works. The price recommended by the Committee was £2000. Mr. Smart moved, as an amendment, that £1750 be agreed to. Mr. Shaw pointed out that the Water Commissioners recently purchased five acres of land on Moncreiffe Island for £800; and he thought £2000 was exorbitant. It was explained that the Gas Commissioners intended to let a portion of the ground, from which they would derive rental sufficient to pay interest on £2000. This sum was afterwards agreed to.

Public men in Perth must be more difficult to manage than they are elsewhere, or they must possess, in an unusual degree, the faculty of not knowing their own minds. They acquitted in a distressingly unbusiness-like way with the proposal to extend the gas-works; and they are treating the extension of the water supply in the same manner. Rejecting the proposal, some time ago, to appoint a high-class engineer, they placed the work in the hands of Mr. Peattie, a local engineer. Mr. Peattie's plans, which were submitted to a meeting of the Water Commissioners on Monday, showed an intake in a gravel bed on an island in the Tay 150 feet above Perth Bridge; and from there an alternative route below the bed of the river to the pumping station in the town. The cost of the two routes was estimated at £4488 10s. and £5878 2s. respectively. With an 18-inch pipe, he considered that a supply of 2,900,000 gallons per day would be obtained; and with a 21-inch pipe, a supply of 4,372,000 gallons per day. He recommended a 21-inch pipe, and that the well at the pumping station should be deepened; the head of 9 feet being, in his opinion,

insufficient. The Commissioners could not agree with Mr. Peattie's proposals, and appointed Mr. Leslie, C.E., of Edinburgh, to report upon them. This is not business. It is ridiculous to expect that Mr. Leslie, a great consulting engineer, will come into the affair and adopt Mr. Peattie's suggestions. A better way would have been to have had a scheme prepared by Mr. Leslie, and then to have employed Mr. Peattie to carry it out. It is altogether a reversal of the proprieties to ask a local engineer to do the important work of preparing a scheme, and then to consult a first-class member of the profession to advise as to the details.

At the recent meeting of the Galashiels Corporation, the Clerk submitted a report on the proposed conversion of debt on the town's water-works. A scheme has been devised whereby a large sum will be saved to the town. The Corporation borrowed £50,000 for the water-works from the Public Works Loan Commissioners, of which there is £45,000 still to pay. The rates of loan were:—On £10,000, 4½ per cent.; and on £40,000, 4 per cent. Having power under a Local Act to pay off the money, the Corporation have contracted for a new loan with the Life Association of Scotland, at the rate of 3½ per cent. The permission of the Council was given to effect this transaction.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, *Saturday.*

I have just been informed that the Purchasing Committee of the Glasgow Gas Trust have this week closed contracts for upwards of 100,000 tons of cannel and other gas coal on very favorable terms. With the purchases made in the spring or early part of the summer, they have now received something like 250,000 tons of coal for the current financial year. In no case, I believe, have the orders to any individual firms exceeded 15,000 tons. The varieties and quantities of coal purchased have been so arranged as to provide the consumers with gas having an illuminating power of from 23 to 24 standard candles. Incidentally, I may here mention that very favorable purchases of coal have also been made by the Paisley Corporation Gas Committee—the average price being, I am told, about 9d. per ton under that of last year. With cheap coal purchases, an increased price for the secondary products, and a very material increase in the consumption of gas, it is confidently anticipated that the present will be a highly successful year for the Paisley Corporation gas undertaking.

Very decided headway is being made by the Dalmuir, Kilpatrick, and Bowling Gas Company throughout the district which is embraced in their area of supply. One part of the Burgh of Clydebank—namely, Clydebank proper—is supplied with gas by the Glasgow Corporation Gas Commissioners, and at the Glasgow price. This circumstance places the Dalmuir Company at a disadvantage, inasmuch as some of their consumers naturally feel annoyed at having to pay a much higher price than that charged for the Glasgow gas. Those of them, however, who understand the question are well aware that the gas supplied by the Company is the cheapest gas in Scotland for any locality similarly situated. The extent of gas-piping throughout the district is probably greater than that of any other Scotch gas company having a similar wake. Since the present owners of the works entered into possession, they have year after year reduced the price of the gas—from 7s. 6d. to 5s. 5d. per 1000 cubic feet; and as the works and plant are capable of providing and delivering a very much larger supply, the consumers can only hope to have the price permanently reduced by supporting the Company as their customers. It is well known that it was by a mere accident that the Glasgow gas supply was extended to Clydebank. The Partick, Hillhead, and Maryhill Gas Company had their mains laid as far as Scotstown, quite sufficient to meet the wants of the district, when the Glasgow gas authorities stepped in, and laid their pipes to Clydebank, without making any extra charge. The district was wanted by the Partick and Hillhead Company; and, in a sense, it naturally belonged to them.

By way of supplement to my "Note" of last week on Dumbarton gas affairs, the following figures may be of some interest. The expenditure of the Gas Corporation for the year ending Aug. 1, 1888, including a balance of £810 7s., amounted to £6021 18s. For coal there was expended £2276 19s.; and for salaries and wages the expenditure was £902 16s. The profit and loss account shows the past year's profits to have amounted to £769 4s. 9d. For gas-rental there was received £5300 3s., which, with arrears and sales ledger account, gave a total revenue of £6021 18s. The total assets are set down at £33,393 15s.; the principal item of which is £31,310 13s.—being the amount expended on the gas undertaking up till Aug. 1 last year. Up to the same date there had been expended in purchasing annuities the sum of £2300 4s.; and during the past year £56 6s. was expended in making further purchases—the total being £2356 10s., which is the amount at which the sinking fund now stands. Amongst the debts of the Gas Corporation, there is an item of £10,350 in the shape of loans on debentures. The sum of £8350 12s. 10d. is set down in the capital account as accumulated profits.

At the beginning of almost every lighting season, the ratepayers of the village of Kilmacolm are made aware that there are amongst them some mean persons. There is no sort of municipal government for the village; and consequently the public street lighting has to be done by voluntary assessment. Last night the ratepayers held their annual meeting to receive a report from the Lighting Committee, and to fix the assessment for the ensuing year. It transpired in the course of the proceedings that, out of 271 ratepayers, only 136 paid assessment for the past year; the rest being quite willing to take the benefit without having to pay for it. It has been resolved to continue the voluntary system for another year; the rate agreed upon last night being 2d. per £1 of rental. A strong feeling is arising in favour of adopting certain portions of the "Lindsay" or Scotch Police Act; so as to cause every ratepayer to bear his due share of the public burdens.

At the monthly meeting of the Kilmarnock Town Council on Wednesday, it was reported by the Gas Committee that Messrs. W. C. Holmes and Co. had completed the extension of the gasholder, and that the enlarged holder was working satisfactorily.

An improvement in the price of sulphate of ammonia, after a long period of depression, is reported by salesmen. A couple of weeks ago the price was about £11 5s. per ton f.o.b.; but this week the quotation has advanced to £11 12s. 6d., while an additional 5s. per ton was asked for forward delivery.

The time for Town Councillors and Police Commissioners to render accounts of their stewardship has arrived; and one of the first to come before his constituents was Bailie Colquhoun, one of the representatives of the Ninth Ward in the Town Council of Glasgow. In addressing a meeting of the electors last night, he said that the gas accounts were in a satisfactory state and were continually growing, so much so that they had been able to reduce the price 2d. per 1000 cubic feet. He proceeded to remark that, in view of the early extension of the city boundaries, negotiations had for some time been going on between the Corporation and the Partick, Hillhead, and Maryhill Gas Company, with the result that, at the next meeting of Council, a proposal would be submitted by the Gas Committee, asking for authority to conclude a bargain between the Corporation and the Company

with a view to the amalgamation of the Company's works with those of the Corporation. He (Baillie Colquhoun) was not very much in favour of taking over undertakings of that sort; but he frankly confessed that a case of hardship had been made out in some respects by the shareholders of the Company before Parliament. If the extension of the city had taken place without some arrangement whereby their works were to be taken over, the shareholders must have suffered loss. However anxious the citizens of Glasgow might be for amalgamation of the suburban burghs, he was sure that not one of them would like to injure the shareholders of a public Company like the one in question; and his hearers would be gratified to know that through the negotiations which he had spoken of, an amicable arrangement, fair to both sides, was likely to be arrived at.

The course of the Glasgow pig-iron warrant market this week has been rather disappointing, especially in view of the satisfactory position of trade. Scotch iron ranged in price between 41s. 5d. on Monday and 40s. 2d. on Tuesday; while the closing price yesterday afternoon was 40s. 8½d. per ton cash buyers. A considerable increase has been made to the stocks in store this week.

Both in the home and export departments, the coal trade of Glasgow and West of Scotland is decidedly active this week. The price of household coal has been advanced 1s. per ton in Lanarkshire and 6d. per ton in Ayrshire; and the increase has very generally been conceded by merchants. Shipping coals are unchanged in price.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Oct. 6.

Sulphate of Ammonia.—The strong market this week has been due to the continued good inquiry from French consumers; and all available parcels have been readily taken off the market at prices up to £11 12s. 6d. f.o.b. Hull and Liverpool, and £11 10s. f.o.b. Leith. Germany, evidently a little frightened at the tone of the market, is now to some extent joining in the requisition for October and this year's contracts; and consequently fair values have been secured by those makers who could make up their minds to anticipate the disposal of their production. Generally, however, makers set their face against entering into forward contracts; and in their decision they appear to fall again into the mistake so often made, of not getting rid of, at all events, a portion of their production when buyers are willing and prepared to accord good prices. This argument is specially applicable now; and it is hardly a reasonable conclusion to draw, that prices will keep advancing at this season of the year. There is a large production coming on; and sulphate will cease to find customers during the months in which it is not absolutely required, if and when quotations rise above the parity of nitrate. The latter has, of course, much to do with the improved position of the sulphate market, although there can be little doubt that "bull" speculation has driven up rates rather more than they would have done in their natural course.

As the nitrate market requires watching—because it will probably direct the course of sulphate during the next few months—a statement of the position of this commodity on the 1st of October this and corresponding years may not be out of place:

United Kingdom and Continent.

Year.	Deliveries during Sept.	Stocks.	Afloat.
1888 . . .	29,000 Tons.	45,000 Tons.	200,000 Tons.
1887 . . .	26,000 " "	19,000 " "	180,000 " "
1886 . . .	24,000 " "	58,000 " "	88,000 " "

This makes the visible supply at date 245,000 tons in 1888; 199,000 tons in 1887; and 146,000 tons in 1886. The price in Liverpool was 9s. 6d. this year; 9s. in 1887; and 8s. 9d. in 1886.

LONDON, Oct. 6.

Tar Products.—The demand for pitch and tar oils is a little better; but other products remain quiet, and in some cases neglected. Prices may be taken as follows:—Tar, according to position, 17s. 6d. to 22s. 6d. per ton. Benzol, 90 per cent., 3s. per gallon; 50 per cent., 2s. 4½d. Toluol, 1s. 9d. per gallon. Solvent naphtha, 1s. 3½d. per gallon. Crude naphtha, 30 per cent., 1s. per gallon. Light oil, 3d. per gallon. Creosote, 2d. per gallon. Pitch, 12s. to 13s. 6d. per ton. Carbolic acid (crude), 3s. 4d. per gallon. Cresylic acid, 9d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 6d. per unit; "B" quality, 1s. 3d.

Ammonia Products.—Sulphate of ammonia is in much better odour; and important sales have been made. Price is firm, at £11 10s. to £11 15s., with an advancing tendency. Prices of other products remain the same as last week: Gas liquor (5° Twaddell), 7s. 6d. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 1½d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £27. Sal-ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, Oct. 6.]

Sulphate of Ammonia.—The market has been very firm indeed during the entire week; and the Continental demand has improved values a little. Supplies are scarce; and even odd parcels only obtained with difficulty at current rates. Beekton price is £11 12s. 6d.; while London outside makes are fetching £11 12s. 3d. At Hull and Leith business has been brisk; the prices at the former port reaching £11 12s. 6d., while at the latter the market may be said to close at £11 10s. While the present demand continues, there need be no fear of prices receding, though it must not be forgotten that the make is increasing as the days lengthen, and requires to be dealt with very cautiously.

Tar Products.—In spite of prognostications of a better state of things, benzoles continue *in statu quo*. It is said that 90's can still be purchased for 2s. 11d., and 50/90's for 2s. 4d.; and the big make will soon be upon us. Solvent naphtha is, on the other hand, very firm, and is expected to remain so for a few weeks at any rate. For 90 per cent. at 160° C., as much as 1s. 5d. is asked, although we have not heard of business above 1s. 4½d. Carbolic acid (crude) is still weak, and there are as yet no signs of recovery; for there are certainly signs that it is losing its ground as a universal disinfectant. Lucigen oil continues to move off freely; while pitch has slightly improved in value—it being stated that Beekton has recently made sales at 15s.

OPENING OF NEW GAS OFFICES FOR THE STAFFORD CORPORATION.—On Monday last week, the members of the Stafford Corporation met the Gas Committee, by invitation of the Chairman (Mr. Alderman Dudley), for the purpose of inspecting the alterations which have recently been made in the gas offices. The visitors were received in the office of the Gas Engineer and Manager (Mr. J. F. Bell), where Mr. Alderman Dudley gave an interesting account of the improvements which have been introduced into the plant during the past five years; alluding specially to the adoption of regenerator furnaces and apparatus for the manufacture of sulphate of ammonia. At the close of the address, the visitors were conducted round the works; satisfaction being shown at the evidences of good management which were everywhere present.

TRINIDAD GASLIGHT AND COKE COMPANY, LIMITED.—This Company was registered on the 2nd inst., with a capital of £100,000, in £5 shares (of which 50,000 are preference shares), to acquire a contract for lighting the Port of Spain, Trinidad, or elsewhere in the West Indian Islands, by gas or other illuminant, and to acquire lands, buildings, collieries, pitch lake, and other minerals in Trinidad or elsewhere.

LONGTON CORPORATION GAS SUPPLY.—At the meeting of the Longton Town Council last Thursday, it was stated that the gross profits of the gas works for the year ended June 30 last were £7238; and after deducting payments for principal and interest, there was a balance of £2263. Of this amount £236 had been set aside for re-sheeting and repairing the gas-holder; leaving a balance of £2027 to go towards a reduction of rates.

THE PROPOSED EXTENSION OF THE BRADFORD WATER-WORKS.—Last week, Dr. C. Meymott Tidy made an inspection, in the company of a Sub-Committee of the Bradford Corporation Water Committee, of the water in the Nidd Valley and in the Grimwith district, from one of which localities it is proposed to obtain an additional supply for the borough. The question of appointing another Engineer besides Mr. A. R. Binnie, the Corporation Water Engineer, to examine the districts, along with the Sub-Committee and Dr. Tidy had been discussed by the Committee, and the suggestion was made that he should accompany Dr. Tidy also; but inasmuch as the latter's visit was purely for chemical and analytical purposes, it was not deemed advisable that any engineering question should be dealt with.

THE PROPOSED PURCHASE OF THE LUTON WATER-WORKS BY THE CORPORATION.—According to the *Luton Times*, no greater surprise has ever come upon the ratepayers than that occasioned by the resolution of the Town Council, at a special meeting last Friday week, to offer £120,000 to the Luton Water Company for the acquisition of their undertaking, to which reference was made in our columns last Tuesday. It was admitted that the Company serves the town well, and that its officials are beyond reproach; and it was not pretended that the borough would gain any immediate benefit. The whole case rests upon the possibility of an increased demand for water in the future, and on the Corporation carrying on the undertaking with the same, if not indeed greater economy, than now characterizes its management. The paper alluded to thinks that such problematical advantages do not justify the Council in forcing the scheme upon the ratepayers without adequate information being laid before them, and full opportunity also for its consideration. It is likely the proposal will cause some excitement at the forthcoming elections.

GWYNNE & BEALE'S PATENT GAS EXHAUSTERS AND ENGINES

PLEASE ADDRESS IN FULL—

GWYNNE & CO.,ADDRESS FOR TELEGRAMS:
"GWYNNEGRAM LONDON."

HYDRAULIC AND GAS ENGINEERS, ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C., ENGLAND.

TELEPHONE No. 2698.

Thirty-three Medals at all the Great International Exhibitions have been awarded to GWYNNE & Co. for Gas Exhausters, &c.

Only Medal at the Liverpool International Exhibition, 1886, for Centrifugal Pumping Engines.

They have never sought to make price the chief consideration, but to produce Machinery of the very highest quality.

The result is that in every instance their work is giving the fullest satisfaction.

They have completed Exhausters to the extent of 24,000,000 cubic feet passed per hour, which are giving unqualified satisfaction in work, and can be referred to.

ONLY 75 REVOLUTIONS PER MINUTE.

The above Engraving shows Two Engines driving Four GWYNNE & CO.'S PATENT NON-FLUCTUATING EXHAUSTERS, to pass 200,000 cubic feet per hour (without the slightest oscillation), at the EFFINGHAM STREET GAS-WORKS, SHEFFIELD.

Can be made, when desired, on their New Patent principle to pass Gas without the slightest oscillation or variation in pressure.

NO OTHER MAKER CAN DO THIS.

GAS VALVES, VACUUM GOVERNORS, REGULATORS, PUMPS, &c., &c.

Catalogues and Testimonials on application at the above address.

OXIDE OF IRON.

THE Gas Purification and Chemical Company, Limited, advise their friends that their only representatives for the Sale of Oxide are Mr. Andrew Stephenson and such Sub-Agents as may be accredited from the Head Office. They further state that the royalties possessed by them extend over an area of more than 350,000 acres, and are held for a long term of years. They employ their own overseers and labourers, and there are no intermediate profits between them and the consumer.

Address 160, 161, and 162, Palmerston Buildings, Old Broad Street, LONDON, E.C.

JOHN WM. O'NEILL,
Managing Director.

ANDREW STEPHENSON, Agent for the GAS PURIFICATION AND CHEMICAL COMPANY, Limited, Palmerston Buildings, Old Broad Street, LONDON, E.C.

CANNEL COAL, &c.

JOHN ROMANS & SON, EDINBURGH. Gas Engineers, supply all the most approved SCOTTISH CANNELS; also FIRE-CLAY GOODS, CAST-IRON PIPES, and other APPARATUS for GAS AND WATER WORKS.

Prices, &c., will be forwarded on application to No. 80, ST. ANDREW SQUARE, EDINBURGH, } SCOTLAND.
No. 54, BERNARD STREET, LEITH, }

GAS-WORKS of any magnitude leased, at premiums ranging from 5 to 10 per cent., according to the size of the Works. Gas-Works erected or re-modelled upon the most modern principles. Address GEORGE WELLER, Gas Engineer, St. Ives CORNWALL.

ADVERTISER desires an appointment as ASSISTANT, CLERK, INSPECTOR, FOREMAN, or in any place of trust. Thorough knowledge of Manufacture, Purification, and Distribution, and is a good Accountant. Young, energetic, and well connected. Good testimonials and references to several well known Gas Engineers. No objection to go abroad. Address 1650, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

SITUATION Wanted, as Traveller or COLLECTOR. Good address. First-class references. Address No. 1651, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

SMALL Station Meter Wanted, to pass 2000 feet per hour; good condition. Send particulars and price to Gas, care of Street Co., 30, CORNHILL, E.C.

WANTED, a Situation as Working MANAGER in Small Works. Thoroughly understands the Carbonizing Department, Reading Indices of Meters, Fixing Meters, Stoves, &c., Laying Mains and Services, and all Repairs attached to Gas Plant. Age 39, married, abstainer. Address No. 1630, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

WANTED, an Iron Tank-Waggon, new or second-hand, capable of holding 6 to 8 tons. Send particulars to NEWTON, CHAMBERS, and CO., LIMITED, Thirlcliffe Iron-Works, near SHEFFIELD.

WANTED, by a large Provincial Gas Company, a competent Engineering DRAUGHTSMAN. Must be able to make Original Drawings; calculate Strains; and get out Quantities, &c. A permanent engagement to a capable man. State experience and salary required to No. 1649, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

TIMMIS & CO., of STOURBRIDGE

Make only the best quality of FIRE-CLAY RETORTS, BRICKS, TILES, & LUMPS. Also SPECIAL SILICA BRICKS, to stand great heats. All descriptions kept in Stock.

For Prices apply to JAMES LAWRIE and Co., 63, Old Broad Street, E.C., Sole Agents for London and District. Telegraphic Address: "EIRWAL, LONDON."

ALEX. WRIGHT & Co., 55, 55a, and 56, MILLBANK STREET, LONDON, S.W.

[Telegraphic Address: "PRECISION LONDON."] Makers of Wet and Dry Gas-Meters, Station Meters and Governors, Photometers, and Gas-Testing Apparatus, Test Gas-holders and Meters, Registering and other Gauges, &c., &c.

** See Advertisement on Page III. of the Wrapper of this week's issue.

W. C. HOLMES & Co., Huddersfield,

ANN 80, CANNON STREET, LONDON, Contractors for Gas-Works complete, Makers of Gas-holders, Purifiers, Scrubbers, Condensers, Retort Fittings, &c., Improved Valves, Engines, and Exhausters. A set for Collingwood's Regenerative Retort-Settings.

** See Advertisement p. 609 of last week's issue. Cablegrams: "Ignitor London." Telegrams: "Holmes Huddersfield."

SULPHATE of Ammonia Lead Burner

and Chemical Works Plumber. Twenty six years' experience. Distance no object. Address P. J. DAVIES, 78, EARL'S COURT ROAD, W.

"EXCELSIOR" TAR-BURNER.

TAR worth 30s. per ton for Burning. See and see and believe, or send for Burners complete, with Instructive and Descriptive Pamphlet, 16s. 6d.

Estimates given for Fixing and Starting, and satisfactory working guaranteed on application to THOS. BURTONSHAW, Gas-Works, CHIPPING NORTON.

WANTED, at once, the following

SECOND-HAND PLANT:—Six 12-inch Δ -shaped Retort Mouthpieces, with Ascension-Pipes and Hydraulic.

Set of 6-inch Pipe Condensers, with box complete. Small Scrubber, and Two 6-inch Byo-Pass Valves. Two 6 feet square Purifiers, with Valves and Connections complete.

About 2000 feet per hour Station Meter, with Byo-Pass Arrangement and Connections. Three 4-inch Slide-Valves.

Prices and full particulars to H. W. FALKNER, Gas-Works, Eye, SUFFOLK.

FOR SALE—A Station Meter, in round

case, to pass 12,000 cubic feet per hour, with Clock, Tell tale, Water-Level Indicators, Overflow and Filling Arrangements, and Byo-pass Valve all complete.

The Meter is being removed to make room for a larger one; and is in first-rate condition. Inspection invited.

For particulars apply to Messrs. JAS. MILNE & SON, Edinburgh (Makers) or to THOS. WHIMSTEN, Gas-Works, PERTH.

NEW ROMNEY GASLIGHT AND COKE COMPANY, LIMITED.

ISSUE OF 400 SHARES OF £5 EACH.

THE above Company, having to supply

with Gas the rapidly increasing watering place Littlestone-on-Sea, have been compelled to construct new Works, and are, in consequence, raising new Capital. Five per Cent. Dividend was declared for the year ending the 30th of April last. Applications for the remainder of the new SHARES to be addressed to

New Romney, Kent.

WM. ALLEN, Secretary.

IRISH BOG ORE OXIDE OF IRON.

GAS PURIFICATION.

BALE, BAKER, & CO., direct Importers from Ireland. Sample and Price on application. Spent Oxide and Sulphate of Ammonia purchased. 120 and 121, NEWGATE STREET, LONDON, E.C.

SULPHURIC ACID.

JOHN NICHOLSON & SONS, Chemical Works, LEEDS, specially produce this ACID for making SULPHATE OF AMMONIA of high quality and colour.

Highest References and all particulars supplied on application.

JOHN RILEY & SONS, Chemical Manufacturers, Hapton, near Acerrington, are MAKERS of SULPHURIC ACID, from Brimstone, for Sulphate of Ammonia making. Highest percentage of Sulphate of Ammonia obtained from the use of this Vitrol. References given to Gas Companies.

ACETATE OF LEAD BOOKS.

TEST Papers and Solutions for Gas- Works prepared by R. D. Gibbs, Summerfield Crescent, Birmingham. Analysis of Coal, Oxide, and all Gas Materials.

BOROUGH OF DARLINGTON.

THE Gas-Works Committee invite TENDERS for the supply of 10 tons of PER-OXIDE OF IRON for Gas Purification, delivered at the Darlington North Road Railway Station; delivery to extend over a period of Three months from the acceptance of tender.

Tenders to state whether the article tendered for is Precipitated Oxide or Natural Bog Ore; also the amount of moisture contained therein, and a guarantee that such amount will not be exceeded in the bulk.

Tenders, endorsed "Tender for Iron Oxide," must be sent to me not later than the 23rd inst. No pledge is given that the lowest or any tender will be accepted.

By order,
F. T. STEVENSON, Town Clerk.
Darlington, Oct. 5, 1888.

PATENTS, DESIGNS, AND TRADE MARKS ACT, 1883.

IN THE MATTER OF Letters Patent granted to ROBERT SOUTHWORTH LAWRENCE, residing at the Corner of 14th Street and Pennsylvania Avenue, in the City of Washington, District of Columbia, United States of America, for "Improvements in Carburettors and Gas Generators." Dated the 28th of December, 1886; No. 16,992.

NOTICE is hereby given that The Lawrence Automatic Gas Company, Limited, of 58, Lombard Street, in the City of London (Assignees of the said Letters Patent), have applied for leave to AMEND the SPECIFICATION numbered as above.

A Copy of the Specification as proposed to be amended can be inspected at the Patent Office, and particulars of the proposed Amendment were set forth in the "Official Journal of the Patent Office," issued on the 29th of September, 1888.

Any person intending to oppose the said application must leave notice of objection thereto (on Form G) at the Patent Office, 25, Southampton Buildings, London, W.C., within one calendar month from the date hereof.

Dated this 29th day of September, 1888.

(Signed) H. READER LACK,
Comptroller-General.
W. LLOYD WISE,
46, Lincoln's Inn Fields, London, W.C.
Patent Agent for the Applicants.

THE JOURNAL OF GAS LIGHTING, WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, OCTOBER 16, 1888.

WATER GAS AUXILIARY TO COAL GAS.

IN commenting last week upon the proceedings at the meeting of the Commercial Gas Company, we referred briefly to the remarks made by Mr. H. E. Jones respecting the advantages of some of the water-gas processes which he found in use in the United States, regarded from the point of view of an English gas manager. The mention of this matter recalls the position taken up some two or three years ago by the JOURNAL with respect to a cognate subject—the disposal of coke in the form of fuel gas. At that time there was a glut of this residual—all the gas-works of the country being choked with unsaleable stocks; and while the consumption of gas was everywhere increasing, there did not appear to be any outlet for the additional weight of coke that was being thrown upon the market every year. It began to look as if

the point of saturation had been attained in respect of coke, while the absorption of gas was still progressive; and in many places the increase of gas consumption, ordinarily hailed with satisfaction by Gas Companies, was positively dreaded by engineers and managers responsible for disposing of the superfluous coke. We have reason to know that in several instances gas managers had already commenced making inquiries as to the possibility of converting their coke into fuel gas for consumption in the immediate vicinity of their works, when the tide turned, and the stocks of coke began to shrink as unaccountably and irresistibly as they had accumulated. When Mr. Jones talks about the possibility of water-gas processes being useful auxiliaries in British gas-works, therefore, he is not speaking of something that has never been thought of before, although the office which he thinks these might fill is different from that already discussed. Water or generator gas processes, as means of getting rid of a surplus stock of coke, having dropped out of sight, together with the condition with which they were evoked to deal, we are left free to discuss them again with reference to the particular application referred to by Mr. Jones.

It is unnecessary to disclaim at the outset any intention of recommending water gas as a substitute for coal gas in any country, much less in the natural land of coal gas. Our position with regard to this matter is the same as ever. Water gas cannot be made here so economically as common coal gas, even at the present low price of liquid hydrocarbons suitable for carburetting. At the same time, it is probable that in most places throughout the United Kingdom it could be made as cheaply as the canal gas which it would equal in illuminating power. In the United States, as is well known, coal and water gas have divided gas engineers into hostile factions, whereof one could not say anything good of the other. The coal-gas men arrogated to themselves the name and position of gas engineers, and would not allow to their enemies any other titles than those of schemers, pirates, and similar terms of opprobrium. The scorn was returned with interest; the water-gas men having a special press "organ" which heaped on the coal-gas party all the flowers of American journalistic satire. The coal-gas people, as the first in the field, naturally regarded the others as interlopers; and the peculiar nature of American institutions favoured the growth of competition between the two systems of gas supply, until their rivalry grew to such a height as to be recognizable on all sides as an unmitigated nuisance. There is not a coal-gas company of any note in the United States that has not been driven to defend itself, sometimes by serpentine methods, against water-gas speculators; and the result of this chronic state of "private war" in the country is that both systems are discredited. The coal-gas companies, while, on the whole, the more stable and respectable of the two orders, have kept up the selling price of gas in order to make their capital secure in the shortest possible time, and also to provide themselves with large "fighting funds" against the inevitable day of conflict. The water-gas systems, ingenious and valuable as some of them are intrinsically, have only too often been made to act as blinds to speculative trickery which the most complaisant admirer of native "smartness" has found it difficult to condone. Financial considerations have accordingly so confused the issue, that until very lately it was practically impossible to say positively what either coal or water gas could and could not do for the lighting of American towns. It was as difficult to glean trustworthy data respecting this, the great gas question of the United States, as to pick up satisfactory political information from the opposing newspapers of the country. One party simply painted itself white, and the other black; and there was the end of it. Latterly, however, gas matters have been gradually settling down. The coal and water gas men have begun to talk sensibly between themselves; and there has been a good deal of exchanging of interests between them. In some places the water-gas people have bought out the coal-gas interest; while in others the reverse process has been effected. In very many instances all feeling and prejudice on both sides have been obliterated, and the only remaining interest has been to do a paying business by selling the most profitable commodity. In this way both water and coal-gas have been brought to their bearings in different localities.

Roundly speaking, the American choice between water and coal gas, when untrammelled by external influences, is determinable by the same kind of considerations that have effected the existing difference between English and Scotch gas. Water gas is indicated, as a physician would say, by

certain considerations, mainly geographical. There may be localities so awkwardly situated with respect to the gas coal-fields, that for them it is a case of water gas or nothing. Such considerations cannot be ignored; but we are free to maintain that dwellers in such places are to be pitied. We are not going to argue the old question of whether lighting gas containing more than 10 or 15 per cent. of carbonic oxide should be permitted by law to be sold. There is a great deal to be said for and against the employment of a useful, but poisonous gas, supposing that nothing better can be obtained at a reasonable figure. At the same time we maintain that the distribution throughout a town of illuminating gas containing upwards of 40 per cent. of carbonic oxide is a course which, however recommended by purely commercial considerations, is open to the gravest objections of another kind, which need not be specified in detail. Fortunately, the cost of the article is a sufficient guarantee that it will not be manufactured for sale in the United Kingdom so long as existing conditions prevail.

Poisonous and costly as it is in its normal state, however, it is easily imaginable that water gas has its special attractions for the gas engineer. To begin with, its production is almost ideal gasification. No handling of the raw material—simple tipping into a hopper; and the production of gas almost illimitable at will. On a corner, 14 or 15 feet square, of a retort-house will stand a gas-generator capable at any time, upon a few hours' notice, of yielding 30-candle gas at the rate of 3 million cubic feet per day. Many of the Gas Companies of the States that have acquired water-gas processes, use them wholly for times of emergency. The existence of a spare generator of this kind in the works is worth to the manager an additional holder and half-a-dozen settings of retorts. The fuel and gas-making material is in the coke-yard; and the carburetting oil can be stored in a tank until it is wanted. In a dozen United States cities the gas consumers never know when they are burning plain coal gas, or the same with a strong dash of water gas. If water gas is ever naturalized in British gas-works, it will be in this way, as an auxiliary to the ordinary process of manufacture; and the advantages of such a resource must be ascertained, in every proposed case, with regard to local conditions. It is impossible to lay down a hard-and-fast rule on the subject, to the effect that water gas either can or cannot be profitably used in a British gas-works. It must depend upon considerations which will require to be stated and satisfied in every individual case. What might answer the purpose in London need not necessarily be convenient for Manchester; nor need Birmingham lead Edinburgh, or Glasgow Liverpool. All that has to be insisted upon for the present is that here is a matter that should not be lost sight of.

THE MEETING OF THE NORTH OF ENGLAND ASSOCIATION OF GAS MANAGERS.

THE North of England Gas Managers' Association met on Friday last at West Hartlepool, under the presidency of Mr. Thomas Bower, Engineer and Manager of the West Hartlepool Gas and Water Company. There was a good attendance of members; and the meeting was in all respects successful. The technical portion of the business comprised the presidential address, which will be found in full in another column, and a paper by Mr. J. Wright, of Stockton-on-Tees, upon increasing gasholder storage by telescoping. One of the most valuable suggestions offered by the President was with reference to the desirability of standardizing particular kinds of gas plant, which is a matter that has already been discussed in the JOURNAL and elsewhere. Nobody seems disposed to make a practical move in the direction of reform, however; and therefore the subject remains open for other Presidents of District Associations to deal with in their turn. Possibly in the course of time something may be done in this matter. Mr. Bower also had a suggestion to make upon the position of District Gas Managers' Associations with regard to The Gas Institute. It is not necessary to agree with everything that is said upon this subject in order to be glad that the attention of engineers and gas managers in different parts of the country is directed to it at this critical time. The paper by Mr. Wright will be of use to gas managers when studying the problem of gasholder extension, as it gives figures applying to the cost of telescoping, such as are not always easy to obtain when wanted. Of course, the paper could not finish without a reference to the Rotherhithe experiment, and to the proposals now in the air for dispensing with the whole or a part of the outer guider-framing of gasholders. As these matters did not enter into the scope of the paper, however, they could not be profitably

gone into. The members afterwards went for a steamboat trip round the port, to inspect the harbour improvements; and finished with a dinner at which they were entertained by the Directors of the Gas and Water Company—eventually separating well pleased with the day.

MR. N. H. HUMPHRYS ON DISTRICT ASSOCIATIONS OF GAS MANAGERS.

MR. NORTON H. HUMPHRYS is Secretary of an important District Association of Gas Managers, and is otherwise well qualified to speak upon the subject which he treats in an article that will be found in another column. Mr. Humphrys remarks truly enough that a short time since there was a flagging in the spirit and vitality of Gas Managers' Associations; but it does not follow that this deplorable manifestation is no longer to be discovered because several fresh Associations have recently been founded. Mr. Humphrys is too sanguine on this point; but whether his optimism is justified or not, it may at least be said that he has gone the right way to work to help Secretaries and Committees of such societies to escape from the reproach of dulness at their meetings. He takes up the theme which we broached when recently discussing the subject of District Associations in general and the new Eastern Counties organization in particular, and lays down the broad proposition that good discussions are the ultimate object and test of the success of the meetings of such societies. In this few will be disposed to disagree with him. He endeavours to set forth the conditions under which good discussions may be expected; arriving at them by the negative process of distinguishing the causes that ordinarily operate to prevent them. It is unfortunately the fact that comparatively few Englishmen, from whatever grade of society they may be taken, are ready public speakers; and the worst of it is that those who might have the most to say are often the most difficult to make talk for other people's benefit. They are apt to take their revenge later, by confidentially informing a few particular friends that they could have said a good deal of a very surprising character if they had so chosen. Hence it is impossible to regard their silence as "golden," according to the proverb. On the other hand, men who have the gift of talking about anything and everything are generally to be found in every society; and very great bores they are. A Gas Managers' Association may be looked upon as in some respects a debating society; and the curse of all debating societies clings to it—that the lion's share of the speaking is left to a small percentage of members. In some Associations this evil is reduced to the minimum by the President asking all the company in turn to offer their opinions upon the subject under discussion; but still it is as idle to attempt to make some men open their mouths as it is to induce others to shut theirs. The article contains references to many other points of interest to members of Gas Managers' Associations, such as the influences which the author calls the "recreative" and the "trading" elements. There is no disguising the fact that many of the members of these Associations do not in reality take the slightest interest in the business for which they are ostensibly called together. It is unnecessary to go further than The Gas Institute for proof of this. How many of the members who journey to these meetings are ever reasonably regular attendants at the sittings for the reading and discussion of papers? Then with regard to the trading element, the subject only needs to be mentioned to show what evils this influence is likely to cause, and as a matter of fact does bring upon all Associations in which it is allowed to get the upper hand. This is a matter with regard to which the sentiments of gas managers in general have undergone considerable change of late years. It is with no want of respect to members of trading firms as individuals that we say that they as a class are better away from gas managers' meetings; and the majority of the well-intentioned among them fully recognize the fact. We do not intend to discuss this matter at length now, however, as a better opportunity for doing so may arise before long.

HOW TO GET AT THE SMALL CONSUMER.

WHEN the Manchester District Institution comes to discuss Mr. James Dalgliesh's paper on the competition of oil and other illuminants with gas, Mr. William Woodward, the Engineer of the Bury Corporation Gas-Works, should be able to make an interesting contribution to the debate. One of the problems of the day is how to get the ordinary artisan household to become a consumer of gas, and keep him when he is once secured. Various methods for attaining this end have been suggested, and some are being tried in a

tentative way. Perhaps the most feasible of these schemes is that of the more frequent collection of rentals, of which great things are hoped, and which, if it can be economically and profitably worked, may bring about a revolution in the ordinary supply of gas. Mr. Woodward seems, however, to be in a fair way to solve the problem on his own account. Last week he was able to gratify the members of the Town Council by informing them that an enormous number of meters which had been standing for six or seven years have recently been connected anew with the service-pipes; and that the consumption of gas was, consequently, largely on the increase. These, we take it, are the results of manufacturing gas economically, and selling it at the lowest possible price. Bury is able to boast of the cheapest gas in Lancashire, and almost in the country; and the Gas Committee find that their labours in this direction lead to an increased consumption, and the bringing back to them of some customers who possibly had abandoned the use of gas in favour of its rival—oil. Mr. Woodward will confer a favour on his brother managers by taking the opportunity we have suggested for enlarging on the subject, and explaining in detail the methods by which the increased sale of gas, particularly to occupiers of small tenements, has been brought about.

GAS TESTING POPULARIZED.

ONE of the French journals devoted to the gas industry has been making merry over a decision come to a few months ago by the Municipal Council of Paris, by virtue of which the public laboratory is thrown open to anyone who is desirous of having his gas tested. The Municipality have already patronized the peripatetic photometer; but this last freak strikes our French contemporary as being particularly ridiculous. As a matter of fact, however, we should be disposed to regard such a resolution as certain to remain a dead letter. It has probably been promulgated with the object of currying favour with the gas-consuming public of the capital, who are chronically aggrieved at the unholy compact between the Gas Company and the Municipality for the division of profits—an arrangement that ought never to have been permitted; but it is obviously only one more of the theatrical *tableaux* in which the Municipality have appeared to be chastising the Company with one hand while holding out the other for the usual subsidy. The announcement of the opening of the municipal laboratory to all consumers who are discontented with the quality of their gas is published in the official municipal *Bulletin*, which also gives, for the first time, the results of the tests made by the regular Examiners. According to this statement (which comprises the results of four testings made during the month of June), the gas sent out by the Paris Company scarcely varied throughout the month; its specific gravity only changing from 0.563 to 0.564. The illuminating power is not given. The average proportion of carbonic acid in the gas was 2 per cent., which accounts in some measure for its density being so high for what is generally understood to be its illuminating value. Heavy hydrocarbons, 3 per cent.; carbonic oxide, 9 per cent.; marsh gas, 43 per cent.; hydrogen, 28.38 per cent.; nitrogen, 14.62 per cent.—these figures complete an analysis which, as *Le Gaz* (the journal above alluded to) ironically remarks, will be of great service to the Paris shopkeepers when they accept the invitation of the Municipal Council to have a sample of gas tested specially for themselves at the public expense. Our contemporary imagines that the idea of the Council in thus throwing open their laboratory to the public may be to dispense with the peripatetic photometer, by inducing consumers from different parts of the city to bring their samples of gas to be tested at the central establishment, just as they do with suspicious comestibles. The whole thing is scarcely worth discussing seriously, save as an example of the troubles of a Continental Gas Company.

It may be mentioned, as a testimony to the originality of Mr. W. Gadd's spiral guide-framing for gasholders, that his application for a patent for this system in Germany, where, as our readers may be aware, the rules are very rigid, has passed the examination for novelty without a single citation or comment.

In the programme of the tenth series of lectures to be delivered before the members of the Chartered Accountants' Students' Society of London during the autumn session, we notice one on the 6th prox. by Mr. Ernest Cooper, F.C.A., on "What is Profit of a Company?" and one on Dec. 4 by Mr. Alfred Lass, F.C.A., on "The Accounts of Gas Undertakings," with especial relation to depreciation, reserve, insurance and sinking funds, and the legislation affecting them.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 694.)

WITH an easier condition of the Money Market, and less apprehension with regard to a run upon gold, the general tendency of the Stock Exchange Markets has been to make a recovery. Foreign affairs, too, are regarded with complacency; aiding the general firmness. Railways, however, have been subject to fluctuation. Business in the Gas Market has been exceedingly quiet, and variations in quotations are few and slight. The Metropolitan Companies are better than they were the week before. Transactions have been fewer; but the prices have been firmer. Taking Gaslight "A," it has been done steadily throughout the week at middle figures; the price never ranging much above or below 250. The "H" stock was in somewhat better favour, and a couple of transactions were marked in it; the quotation showing an advance of 1. A little was also done in the debenture and preference stocks, at about average prices. South Metropolitans furnished a little business early in the week; but afterwards were quite neglected. The prices marked were not very good. Hardly anything has been marked in Commercial; but the stocks are in very good favour (regarded by the light of the latest accounts), and there is a growing disposition to buy. Among the Suburban Companies, Brentford furnishes the only item of interest. After a period of stagnation there has been an inquiry for it; and the old stock has changed hands two or three times at good marks. The quotation shows an advance of 2. Some of the Foreign undertakings have not been doing quite so well as lately. Imperial Continental has sustained a slight check to its advance, and has receded 1. Oriental, too, has had a relapse. San Paulo, on the other hand, has advanced; and Monte Video has been firm. The Water Market is very flat; and the disposition to a fall which was observable the week before has been realized in fact. New River dropped suddenly to 340 on Thursday. Lambeth were in equally bad odour; and the 10 per cents. and 7½ per cents. receded 5 and 6 respectively. Grand Junction is put 1 lower; but the other Companies have so far maintained their position.

The daily operations were: On Monday, business in Gas was very restricted. South Metropolitan "A" was the most dealt in, and at middle prices. Oriental fell ½. In Water, nothing was touched but Grand Junction; and that declined 1. On Tuesday, Gas business was more brisk; and many issues were moderately dealt in. The only variation was a fall of 1 in Imperial Continental. In Water, the only transaction was one in West Middlesex, at top price. On Wednesday, the business in Gas was reduced to almost the smallest proportions, and quotations stood unchanged. Water began to fall—New River receding 2½; Lambeth 10 per cents., 2; and Lambeth 7½ per cents., 3. On Thursday, there was a little more activity in Gas; and Brentford old advanced 2. Water was again very flat. Both the Lambeth issues fell 3; and New River buyers were 5 lower. Friday's Gas business was extremely restricted; and prices underwent no change. Water was quiet; but showed no sign of recovery. Saturday's business was of the usual moderate character. Very little was done in Gas; and nothing at all in Water. All quotations closed without variation.

ELECTRIC LIGHTING MEMORANDA.

AWARD OF THE VOLTA PRIZE TO M. GRAMME—STATEMENT BY THE ANGLO-AMERICAN BRUSH COMPANY—PROMISED REAPPEARANCE OF THE SUN LAMP—AN AUDACIOUS STATEMENT.

IN 1882 a French ministerial decree was promulgated relative to a competition which closed on July 31, 1887, ordering that a reward, entitled the "Prix Volta," should be bestowed upon the author of "the discovery which shall render electricity fit to be employed economically in one of the following applications—a source of heat, light, chemical action, mechanical power, means of transporting despatches, or treating the sick." A Commission, nominated by the Minister of Public Instruction, was charged with the duty of selecting, among the authors of recent discoveries in the domain of electricity, him who had the best claim to such a prize. The Commission was composed of 19 eminent French men of science, who have at length decided, "having inspired themselves with the motives which directed the initiative of the Government," to award the prize to M. Zénobe Gramme, for the progress made by him in the construction of dynamo-electric machines. The report presented by M. Mascart, in the name of the Commission, setting forth the reasons for the selection of M. Gramme for this distinction, was published in a recent issue of the *Journal Officiel*. It is herein stated that M. Gramme, then a carpenter by trade, was chosen in 1860 by M. Van Malderen as a modeller for the Alliance Society. He set himself to master the nature of the strange machine at which he worked; and went two years later into Rhumkorff's workshops, where he was employed in mounting electrostatic machines upon wood frames. At this time Gramme bought an elementary treatise upon physics, which he read by the aid of a dictionary, and discovered that many of the hypotheses with which he thus became acquainted were like those he had already imagined in his own mind. This was an encouragement to the worker-student to persevere. His first patent was dated Feb. 26, 1867; and it had reference to improving the alternative-current machine. But want of means hindered him from proceeding with his invention, and he was anticipated by the communication of Wheatstone to the

Royal Society of the principle of the auto-excitation of these machines. The following year M. Gramme constructed in London his first continuous-machine, which did not succeed very well. In 1869 he made a new machine, which was more satisfactory, and contained the first true "Gramme ring," of which so much has since been heard. Lacking means to take out a patent, the inventor applied to M. Breguet, renowned for benevolence as well as for skill in mechanics. M. Breguet pooh-poohed the whole idea; but gave Gramme the 100 francs required for taking out his patent. The notion of this invention had to a certain extent been anticipated by M. Paccinotti in 1864; but M. Paccinotti was a professor at Pisa who had no notion of turning his discovery to practical advantage. Moreover the Commission do not believe that Gramme ever had the chance of reading the obscure memoir in the *Nuovo Cimento* in which Paccinotti's notion was buried. At all events, to Gramme is due the credit of surmounting the material difficulties, the absence of resources, and the incredulity of competent men which combined to obstruct his efforts. In 1869, Gramme designed four types of machines; in 1871, his four-pole machine was presented to the Académie des Sciences by M. Jamin, and was exhibited at work by Messrs. Mignon and Rouart. He followed up, point by point, the study of the construction of these machines; obtaining possession of formulae for proportioning their parts to suit special requirements. Then came his great triumph. From 1854, MM. Christophle had been trying without success to adapt magneto-electric machines for electro-plating, in place of the cumbrous and unhealthy batteries; and hearing of M. Gramme's work, they set him a problem in this line in 1871. Within three months the ex-carpenter delivered a machine that fulfilled the conditions; and the future of electro-deposition of metals was revolutionized. As the report says: "The discovery of Volta was resting in the laboratories. Its industrial applications were very limited, in spite of all the efforts and hopes that arose from Faraday's discovery. Since the labours of M. Gramme, electricity has taken its place in industry beside steam, and its part expands from day to day." It is another striking story of a man who has risen, and will figure in the collection of a successor to Mr. Smiles.

A curious statement, in the nature of an interim Directors' report, has been issued by the Manager and Secretary of the Anglo-American Brush Electric Light Corporation, Limited. It is ostensibly circulated in view of the many important events which have happened during the past few months, but looks very like a device for inviting the confidence of the proprietors in advance of the publication of the usual report and statement of accounts. The principal topic of the circular is the passing of the Electric Lighting Act Amendment Bill, which is patronisingly accepted as better than nothing, although falling short of what the Board would have liked. Such as it is, however, the Act is cited as the justification for the creation of the Chelsea Electricity Company, in which the Corporation are interested as contractors for the generating plant. The goodwill of the public is bespoken for this venture. It is stated that the Company propose to put down plant in the first instance for supplying 6000 lights. The electricity generated at the central station will be conveyed by underground wires to sub-centres, where accumulators, to be supplied by the Electrical Power Storage Company, will be charged thereby. From these storage stations the current will be distributed to the surrounding buildings—if the residents like it. The Brush proprietors are also cheered up by the statement that the Directors have made arrangements for establishing central stations at Bournemouth and other places; and also that the negotiations with the Commissioners of Sewers for the electric lighting of the City of London have been resumed with every hope of a satisfactory issue. From all which we shall be rather surprised if the accounts, when published, are not such as to call for a further exhibition of patience and hopefulness on the part of the shareholders.

It is stated in an electrical contemporary, that after having been subjected to an eclipse of altogether unnatural duration, the *lampe soleil*, at one time tolerably well known in this country under its literally translated title of "Sun Lamp," will shortly reappear in the electrical firmament. This is the arc lamp in which the light is obtained, not exactly from the points of the opposed carbons themselves, but from a block of marble interposed between them, which becomes incandescent, with a very pretty effect. The light is a much better colour than that of the naked arc; but, as originally introduced, the lamp named after the luminary of day was rather a caricature of the steadiness of its fancied prototype. Now, however, it is admitted that all kinds of electric lighting appliances have been much advanced since the last "Sun" lamps shone more or less unsteadily before the eyes of a critical public; and the gear of the lamp itself is said to be so much improved that its reappearance is expected to be something of a triumph. Unfortunately, all this recommendation in advance only reminds one of the common practice in trade by which the successor of a bankrupt shopkeeper, if he intends to carry on the same kind of business, is careful to announce that on a certain day "this establishment will be reopened under entirely new management; and the proprietor hopes by strict attention," &c., &c. At all events, we are by no means disposed to worship the rising sun until, like the moon in "A Midsummer Night's Dream," it can be truly described as "shining with a good grace."

A contemporary records the thrilling fact that 150,000 arc lamp carbons are burnt daily in the United States, of which 100,000 are made in Cleveland, Ohio. Six years ago, all the carbons required for the country were made in a single room in Boston. Now there are 20 carbon-furnaces in Cleveland alone. There is nothing like

a good round figure for striking the average newspaper reader. We fancy, however, that our esteemed electrical contemporary must have unwittingly turned up an old story, for we distinctly recollect having met with the same statement before—a year or two ago. If so, to correct it should require the duplication of the principal figures, after the plan hit upon by Talbot Champneys, in "Our Boys," for bringing the vital statistics of Mesopotamia up to date. How singular, a student of these "facts for the times" might exclaim, that the consumption of electric carbons in a vast region like the United States should work out to such handy even figures; so convenient for the memory, too! Sure to come in suitably in a speech at a meeting of an electric light or gas company. Let us conceive a parallel to it which will be just as authoritative. "It is asserted that exactly 5 million matches are struck every day for lighting the gas-burners required for lighting, cooking, and heating in the United Kingdom. Of these about one-half go out before they can be used; but as, again, an equal number are made to light two or more burners, the average of one match to a gas-burner is restored. Twenty years ago not more than one-half the number of matches were required for this purpose. (N.B.—Matches and gas were then both dearer.)"

A NEW COMBINED SYSTEM OF GAS LIGHTING AND VENTILATION.

At the new establishment of Messrs. W. Sugg and Co., Limited, Westminster, there is now on view an interesting system of gas lighting combined with ventilation, which should be seen by all who desire to keep abreast of modern progress in the utilization of gas. This exhibit should also be specially attractive to custodians of libraries, picture galleries, public halls, churches, and, in short, of all such places in regard to which the electric light is generally prescribed on account of its possession of those qualities of not heating or altering the normal composition of the air, which cannot be claimed for gas as ordinarily employed for lighting. The admitted costliness of electric lighting is commonly excused on the score of its supposed superiority to gas in the matters of cleanliness and healthiness. It is, therefore, with considerable satisfaction that we are able to cite Messrs. Sugg's present display as something which people who are tempted to patronize electric lighting, notwithstanding its expense and unreliability, should make a point of seeing before finally making up their minds to abandon gas. The system in question is due to the joint labours of Mr. John Methven, universally known in connection with the invention of the photometrical standard of light which bears his name, and Mr. W. Sugg. It has been under the process of incubation for a long time; but now it is considered perfectly fit for general use, a protracted series of experiments having shown what difficulties may be expected in its application, and also how to overcome them. The foundation of the system is the discovery of Mr. Methven that the moisture ordinarily present in atmospheric air is prejudicial to the illuminating power of gas burnt by the aid of such air. It does not need much argument to show that, in such a climate as that of the British Isles, this consideration is frequently likely to be a very serious one. As a matter of fact, we believe the air of these Islands usually contains so much aqueous vapour that, according to Mr. Methven's experiments, drying it will improve the illuminating power of gas-flames burnt in it by from 10 to 15 per cent. Generally speaking, therefore, the greater the proportion of aqueous vapour present, the worse the light of gas burnt without artificially drying the air; and, conversely, the greater benefit is derivable from this process. The deteriorating effect of aqueous vapour upon the illuminating power of gas must be due to the capacity of the vapour for heat, resulting in lowering the temperature and correspondingly diminishing the brilliancy of the flame with which it is brought in contact. Thus it would appear that damp weather has a depressing effect upon gas-flames, just as it undoubtedly has upon human beings. If this conclusion is accepted, however, it follows that artificially-dried air can only be supplied to gas-flames when these are protected from the raw external atmosphere by hermetically closed glasses. We are brought face to face, therefore, with a condition of things which requires to be thought over. Supplying gas-flames with dried air means that the gas must be burnt in close globes; and, more than this, that the air supply to the interior of these globes must be conveyed through pipes just in the same manner as the gas itself.

It cannot be denied that at the first glance this will be admitted to be rather a "staggerer," as Mr. Richard Swiveller would say. One has encountered so many improved systems of gas lighting depending upon a special supply of air; and these have all done so badly in the long run, that one is decidedly inclined to regard this requirement in the Methven and Sugg system as something prejudicial to its success. The objection fades, however, upon closer study of the circumstances of the new system. It may be at once conceded that if all the paraphernalia of a separate air supply delivered to the point of combustion through pipes were required merely for increasing the illuminating power of a gas-burner by from 10 to 15 per cent., the prospects of such a system of improved gas lighting would be poor indeed. There is much more than this difference of duty between whole classes of gas-burners actually in use for public and private lighting; and the fact does not prevent a huge business being done in the less efficient burners. It is evident, therefore, that if this was all that could be claimed for the new system, it would be idle to expect that any number of consumers would think it worth while to obtain it at the expense of a second set of pipe-fittings

and an air-blower. Here, however, comes in the second clause of the invention, which has reference to ventilation. The dry-air supply can, of course, do good service in connection with any kind of burner; but as it depends essentially upon a question of temperature, those burners that display the effect of raised temperature most conspicuously are naturally those to which the Methven system is most applicable. These are the regenerative burners. Not only are burners of this class best adapted for showing the economy of heat due to drying the air required for combustion, but they also lend themselves very conveniently to being supplied with air by some special means. They ordinarily take their air at a certain point, and through small holes in a plate well up out of the way of the light; so that it is no trouble, nor does it interfere one iota with the general appearance of the lamp, to cover the air-holes with a chamber in connection with an air-supply system. How material this consideration is, may be perceived by referring to the case of ordinary open Argands and flat-flame burners, and trying to hit upon a plan for supplying these with air delivered from a pipe, without spoiling their appearance. Similarly also, the regenerative lamps are, as it were, made for emptying their products of combustion through chimneys communicating with the outer air. The simple, but, under ordinary circumstances, frequently the insuperable difficulty in the way of rendering this class of gas-burners self-ventilating, lies in ensuring a constant, sufficient, but not excessive draught from the point of combustion to the outer point of discharge. Large and expensive flues, laid with all possible regard to the demands of the effluent gases, do not always succeed in inducing them to go in the way desired. Sometimes it is all right; but it is often very much the reverse—and what is a greater trouble than a ventilating burner that obstinately refuses to ventilate? Here comes in the great utility of the separate air supply. The air is delivered to the point of combustion at a very little above the ordinary atmospheric pressure. There is nothing like a blast, which therefore distinguishes this from previous attempts to which it may be superficially likened—such as the Clamond or the Lewis system. Slight as the increase of pressure may be, however, it is a positive constant impulse which, coming as it were behind the heated gases escaping from the burner, irresistably pushes them forward and out at the appointed outlets. The effect of this is seen in the fact that the tubes conveying the waste products of combustion from the most powerful regenerative burners may be laid almost anyhow and taken anywhere, with the sole proviso that a drain shall be made for the escape of the water of combustion, which rapidly condenses in the flues. The ventilating burners must act properly; no back-current being possible, because of the steady push of the fresh dry-air supply. The result of all this is that in a library or public hall the pure, abundant, cheerful, and reliable light of gas may be obtained without involving the contamination or over-heating of the atmosphere by the products of combustion; and this without running any risk of a reversal of the currents, though a hurricane might blow outside. Natural ventilation—that is to say, ventilation by means of exhaust flues—may answer very well sometimes; but where it will not serve (which is often) what is to be done that can be called better than this? Here we have a combination of perfect ventilation with an additional 10 to 15 per cent. of light thrown in.

Of course, there are many ways in which the supplementary air supply can be obtained. In most great public buildings there is steam or gas-engine power to blow the bellows of an organ or perform other work; and this can be made to supply air for the Methven-Sugg system of lighting at but nominal cost. Where neither steam nor gas power is available, a water motor can be easily fitted up for this service. At Messrs. Sugg and Co.'s factory the system is shown working in a cellar, which is brilliantly illuminated by Cromartie lamps, and would soon become unbearably hot but for the complete ventilation. Here the air is driven forward by a pair of alternating bellows worked slowly by a water motor, which arrangement is very suitable for general shop or warehouse use. It is quite automatic. Turning off the lamps causes stoppage of the motor, which starts again as soon as any air is drawn off for the lamps. A large Cromartie lamp gives a most brilliant light, with a consumption of 20 cubic feet of gas per hour; the duty being after the rate of 11·37 candles per cubic foot when burning with undried air. Supposing the improvement of light due to the drying of the air to be only 10 per cent., this lamp would give a duty of 12·50 candles per cubic foot. As, however, carbonic acid as well as moisture are arrested by the Methven system, it would be probably safe to say that, with such a large lamp as the above, the improvement would be at least 15 per cent. on an average, which would raise its duty to 13·06 candles per cubic foot with nominally 16-candle gas. This we believe to be an unparalleled result. Air is supplied to these burners at the rate of 10 cubic feet to the cubic foot of gas. Supposing every 10 cubic feet of air to contain 2 cubic feet of oxygen and 8 cubic feet of nitrogen, it will become apparent how great must be the difference to any gas-burner between receiving this supply, including so much useless diluent, pure and dry, instead of damp and foul. At the factory, every facility is afforded for following the course of the air and gas and waste products. Meters and pressure-gauges are fixed to the two services, so that an observer may make his own tests, and draw his own conclusions upon the results. It should be remarked that one essential point in the success of these experiments has been the governing of the air as well as the gas at the point of combustion. Air, of course, has no self-propelling power that can take it, like gas, to every part of a complicated

system of pipes. It must be propelled by sufficient power behind it, so that the air-pipes may show a pressure of 2 or 3 inches near the bellows, which only gives about a tenth at the last burner. Hence all the burners must be governed. We understand that the system is to be exhaustively tried on a large scale in several places, notably in the Crystal Palace theatre, where it is expected to realize considerable economy as well as greatly increased comfort and security behind the footlights. It goes without saying that the first cost and working expense of the system are both much below that of any system of electric lighting, with which alone it can be properly compared. It should be stated that although the system only contemplates in the first place the ventilation of the gas-burners, it is only a question of enlarging the air-propelling part of the plant to enable it to supply fresh air, heated or cooled according to the season, to any part of an auditorium or other interior. All these advantages require to be fairly weighed when the prospects of the system are investigated.

SERIOUS ILLNESS OF MR. G. W. STEVENSON.—The professional friends of Mr. George Wilson Stevenson will be grieved to learn that he is now completely laid aside from work by a complication of disorders, prominent among which are congestion of the lungs and heart disease. Upon inquiry at Mr. Stevenson's offices yesterday, we were informed by Mr. E. Herbert Stevenson, who has been for about five years associated with his father, that no favourable change had taken place, and that his condition was such as to preclude the hope of his ever being able to resume the position in the gas engineering world which he has hitherto occupied.

PRESENTATION TO MR. W. R. CHESTER.—On the occasion of Mr. Chester visiting the Bradford Road works of the Manchester Corporation last Saturday, for the purpose of introducing the new Manager (Mr. S. Barratt, of the Rochdale Road works, who will henceforth have charge of the two stations) the *employés* took the opportunity of presenting him with a handsome tea-urn and an illuminated address. Mr. Tatton, the assistant, in presenting the testimonial, referred to the great esteem in which Mr. Chester was held, and the regret the workmen felt at parting with him. He said he was a pre-eminently truthful man, and he would have the truth from those that served under him; and they all hoped he would be long spared to render the same valuable services to Nottingham that he had done to Manchester. Mr. Chester, in reply, said the handsome piece of plate and the testimonial containing so many signatures were more than he expected or deserved. If there had been any shortcomings on his part during the years he was with them, he hoped they would overlook them. He had always tried to do his best between man and man, his employers and the *employés*. He would always look back with pleasure to his association with them, especially with regard to their Mutual Aid Society, to the funds of which he would still contribute. He concluded by thanking them all for the kind wishes they had expressed for himself and family.

THE GLASGOW CORPORATION AND THE PARTICK, HILLHEAD, AND MARYHILL GAS-WORKS.—As will be seen from the report in another column, the proposal to transfer the works of the Partick, Hillhead, and Maryhill Gas Company to the Glasgow Corporation Gas Commissioners came formally before the Town Council last Thursday, but was considered with closed doors. The negotiations in connection with the transfer have been going on since February last year; but in quite an informal manner. Eventually, however, the two parties to the negotiations were enabled to arrive at a common understanding on the matter; the result being the presentation to the Town Council of the report which is given in full elsewhere. The minutes embodying this report formed the basis of the discussion *in camera*. A full statement was made by the Lord Provost (Sir J. King); and the Town Clerk (Sir J. Marwick) read a report which had been received from Mr. T. Hawksley as to the value of the works of the Company as a going concern. He also submitted a report on the same subject from Mr. W. Foulis, Engineer-in-Chief to the Gas Commissioners, who made a comparison between the terms agreed upon in the negotiations and those paid to the Glasgow Gaslight Company and the City and Suburban Gas Company, when the gas supply of the city and suburbs passed into the hands of the Corporation in 1869. Whereas the price paid to the two Companies in that year was about £35 per million cubic feet of gas manufactured, the price agreed upon with the Directors of the Partick, Hillhead, and Maryhill Company is only about £23 or £24 per million. Some opposition to the terms mentioned was offered by Bailie McFarlane, a prominent member of the Gas Committee, who held that the price was £60,000 in excess of what it ought to be. As stated elsewhere, no resolution was come to; the desire being to have a full and unfettered discussion of the matter in all its bearings. The question will, however, come up again next Thursday at an open meeting of the Council, when it is anticipated that a decision will be arrived at so far as the Gas Commissioners are concerned; but, of course, it will have to come before the Company's shareholders. The subject was freely discussed during last week, both on 'Change and by the citizens generally; the prevailing feeling among the members of the Council being to accept the proposals of the Sub-Committee by whom the negotiations were conducted. In the event of the forthcoming Boundaries Extension Bill being passed, and the purchase proposals being carried through, the works will at once become the property of the Gas Commissioners; but it is not expected they will be kept in their present state for more than a couple of years.

Notes.

AN INSTANTANEOUS BOILER.

MM. Serpollet Frères have introduced an instantaneous boiler for steam raising, which was described by M. Lesourd at a recent meeting of the French Society of Civil Engineers. The idea of the makers of this particular form of boiler was to prevent overheating and priming; and to this end they squeeze between two heated surfaces the globular drops as fast as they are formed, and so to bring them into immediate vaporization. For this purpose they employ a cylindrical tube of iron of convenient diameter and considerable thickness, which is passed through rolls at a temperature just below the melting point of the metal, so that it is flattened out, and the internal surfaces are brought as closely as possible together. The open space which is left in the interior of the flattened tube appears in cross section as a black line of the thickness of a hair. The tube thus prepared may be bent into any shape most convenient to the space in which it is to be heated—as circular, square, or oblong spiral—each end being connected to a tube, the one an inlet for water, and the other an outlet for steam. The boiler is then complete and ready to work. It is heated up to about 250°C ; and when water is forced into one end, steam is collected at the other under a pressure, and with a degree of dryness, according to the temperature. The water-feed is supplied by a small force-pump, and it is stated that any matters dissolved in the water are reduced to an impalpable powder, and expelled with the steam. The arrangement for the feed water is made to regulate itself, which it does easily, and apparently with a very methodical utilization of combustible, which, however is admittedly a question to which M. Lesourd must return when further experiment has determined the necessary data. The maintenance and supervision of the boiler will be reduced to nothing, since it does not contain any riveted joints or a safety-valve. In the extreme case of rupture of the tube, there would not be any projection of the tube or its contents, because the steam exists in too small a volume to possess any projective power. In recent trials made before the *Ingénieurs des Mines*, the tube was not ruptured, although the steam-pressure was pushed to about 800 atmospheres. For small and domestic motors, this type of boiler is claimed to possess many advantages, as it will make steam machinery as safe and easily looked after as gas-engines. For small boilers of from 0.5 to 2 horse power, the tube before flattening is 55 millimetres in diameter and 11 millimetres thick. After rolling, the internal water space measures 0.1 or 0.2 millimetres in width. A 1-horse power boiler, when finished, is a tube 2 metres long, 0.105 metre high, and 0.022 metre wide, weighing 32 kilos., and offering a heating surface of 0.48 square metre. Its internal capacity is only a few cubic centimetres; and the whole arrangement, with its furnace, weigh 130 kilos. This model evaporates 20 kilogrammes of water per hour with a fuel consumption of 3.750 kilos. It is intended to fit up these boilers and furnaces with engines and dynamos on one base-plate for small electric light installations.

THE COMPRESSIBILITY OF GASES.

M. Amagat has communicated to the *Comptes Rendus* some observations upon the compression of gases—comprising oxygen, hydrogen, nitrogen, and air—to pressures reaching 3000 atmospheres. The author remarks that his results differ considerably from those published by Natterer, since for the same reduction of volume of the gases observed, he has generally found the pressures to be very much greater than those given upon Natterer's authority—a result which he ascribes to the probable and even inevitable errors of the processes adopted by that experimenter. M. Amagat finds that at a pressure of 3000 atmospheres, and at a constant temperature of 15°C ., a volume of the following gases which is equal to unity at the ordinary temperature occupies the following spaces:—Air, 0.001401; nitrogen, 0.001446; oxygen, 0.001235; hydrogen, 0.000964. Under extreme pressures, oxygen, nitrogen, and air have nearly the same compressibility, which is according to the room occupied by the liquids. At 3000 atmospheres it is about equal to that of alcohol under the normal pressure. The compressibility of hydrogen is much greater—nearly double, in fact. At 3000 atmospheres it is nearly equal to that of ether at about the normal pressure. The densities of these gases when compressed to 3000 atmospheres are given as follows by M. Amagat, water being taken as unity:—Oxygen, 1.1054; air, 0.8817; nitrogen, 0.8293; hydrogen, 0.0887. These values have been determined by assuming the number generally admitted for the compressibility of the glass envelopes of the liquids.

THE HARDENING OF MORTARS AND CEMENTS.

In an article recently published in the *Engineer*, the hardening of hydraulic cements is discussed from the chemical point of view. It is remarked that many of the substances commonly known by this description are mixtures of considerable complexity, and that the most reasonable method of investigating their behaviour in regard to setting or hardening is to examine every constituent or individual compound separately, in order to discover how the combination of these constituents acts when they are all mixed together. Plaster of Paris is the simplest of this class of substances, consisting as it does of baked or burnt gypsum, setting into a hard mass when mixed with water. The only chemical change effected in gypsum by heating is deprivation of the water which it contains in its native state as a stable crystalline form of hydrated calcium sulphate. In the process of setting, the particles of

plaster which come into actual contact with the water are immediately converted into particles of gypsum, which dissolve in the water; but the water very soon becomes supersaturated with gypsum, and consequently crystallization suddenly takes place, with deposition of the gypsum in a peculiar form of crystal, and setting free more water to take up more gypsum to be crystallized out in turn. These crystals assume the form of extremely attenuated needle-like prisms, which unite to constitute little spherical groups. These groups of very fine crystals fulfil all the conditions for forming a hard mass of gypsum out of the plaster and water, inasmuch as they expose a great surface for extensive adhesion, and permit of much interlacing. The next cements in order of simplicity are aerial cements and mortars, consisting of mixtures of slaked lime and sand. Neither slaked lime nor sand undergoes any chemical change when mixed with water by itself; but some change is produced when they are mixed together in the presence of water. Little or no chemical change takes place under the circumstances. The hardening of these cements is attributed in the first instance to mere desiccation; the sand acting simply as a binding material to prevent crumbling and cracking. Aerial mortars undergo in time a second hardening, due to the action of the carbonic acid of the air, which results in the formation of carbonate of lime. The action of hydraulic cements and limes and puzzolanas is a much more complicated matter. In mere mixtures like the aerial mortars, silica and lime neither combine with one another nor act under water; but in hydraulic cements they do both—showing that they exist in the latter in other conditions. The great difference is that, whereas in aerial mortars both the lime and the silica are in the free state, in hydraulic cements these substances exist in chemical combination as silicates of lime. The setting of cement depends upon the liberation of calcium hydrate and the formation of hydrated silicate, which does not decompose in the presence of the calcium hydrate, but goes through the various changes culminating in the production of extremely attenuated prisms, exactly as in the case of plaster of Paris.

THE MANAGEMENT OF THE HALIFAX GAS-WORKS.—There were 38 applications for the post of Gas Engineer and Manager to the Halifax Corporation, rendered vacant by the resignation of Mr. W. Carr. These were reduced to four; and last Friday the Gas Committee made their final selection—Mr. Thomas Holgate, F.C.S., Manager of the Batley Gas-Works, being appointed.

THE TOWN CLERKSHIP OF SALFORD.—Mr. S. Brown, Town Clerk of Rotherham, has been appointed Town Clerk of Salford at a salary of £1000 per annum, in succession to Mr. John Graves, who, it will be remembered, has absconded. There were 72 applicants for the appointment; and these were reduced, by a Special Committee, to three, whose names were submitted to the General Purposes Committee. After a sitting of two hours, they selected Mr. Brown.

AWARDS AT THE BRUSSELS EXHIBITION.—Among the awards to the British exhibitors at the Brussels Exhibition we notice the following:—Gold Medals: Doty Lighting and Heating Company, Limited, for petroleum-lamps; the Fourness Regenerative Lamp Company for gas-lamps; the Wenham Company, Limited, for gas-lamps. A diploma of honour has been awarded to Mr. S. Lee Bapty, who has had the entire supervision of the British Section of the Exhibition, which, it may be remembered, was the first to be completed.

ACCOUNTS OF GAS COMPANIES AND CORPORATIONS FOR 1887-8.—Just before going to press we received a copy of the "Analysis of the Accounts of Gas Companies and Corporations for 1887-8," published by Mr. John Allan. Of course, we have not had an opportunity of verifying the accuracy of the figures; and can therefore only say that the accounts of thirty-four of the principal Gas Companies and Corporations are dealt with, and that in general appearance the book is similar to that issued last year, of which a notice appeared in the *JOURNAL* for Sept. 20 (p. 535).

THE BIRMINGHAM ELECTRIC LIGHTING SCHEME.—After the election of the Mayor and the transaction of ordinary business, the annual meeting of the Birmingham Town Council on the 9th prox. will be made special, to consider a notice given on behalf of Messrs. Chamberlain and Hookham of their intention to apply to the Board of Trade for a Provisional Order empowering them to supply electricity for public and private purposes in the area within the jurisdiction of the Council, to determine whether the Council shall consent to or oppose the grant of such Order, and to authorize the General Purposes Committee to take measures for carrying out the decision of the Council.

AMERICAN GASLIGHT ASSOCIATION.—As already announced in the *JOURNAL*, the annual meeting of this Association will take place at Toronto this week—the proceedings opening to-morrow with the Inaugural Address by the President (Mr. T. Turner, of the Charleston Gas-Works), and extending till Friday, which day will be devoted to a drive round the principal parts of the city and suburbs. In addition to the papers mentioned in the preliminary programme of the arrangements for the meeting issued by the Secretary (Mr. C. J. Russell Humphreys), and noticed in the *JOURNAL* for Aug. 28 last, a communication on "Enriching Gas with Naphthalene," by Mr. A. Kitson, will be presented; and the latest forms of Herr Lux's gas-balance will be exhibited and described. The offer of a prize of \$25 by the Association for the best paper on "Naphthalene" will be a special feature of the forthcoming meeting.

Communicated Articles.

DISTRICT ASSOCIATIONS OF GAS MANAGERS.

By NORTON H. HUMPHREYS, Assoc. M. Inst. C.E., F.C.S.

It is only a short time since that a flagging in the spirit and vitality of Gas Managers' Associations appeared to be prevailing. A feature at almost every meeting was a complaint from the Chairman as to the difficulty of obtaining papers; and many persons formed an opinion that every debatable topic in connection with our industry had been talked to death. But lately a change has been noticeable. Not only have existing Associations shown signs of vigorous existence and growth, but there has been a growing sense, both in Europe and the United States, in districts unrepresented by the Gas Managers' Association, as to the desirability of remedying this defect. The result has been the formation, within the space of a year or so, of the North of Ireland, of the Eastern Counties, of the South-West (U.S.A.), and of other Associations. The writer has been brought very intimately in contact with the working of a Gas Managers' District Association for several years past, and proposes to note in this article a few ideas thereon that have occurred to him as the result of his experience.

The main, indeed one might almost say the sole object of District Associations, is the holding of meetings. Incidentally, they are capable of discharging other useful offices, as circumstances may necessitate from time to time; but the meeting is the chief idea. It may therefore be taken that the prosperity of the Association as a body will be influenced by the success of the meetings. If we ask, What constitutes a successful meeting? the answer will be, "Good discussions." The Gas Managers' Association is not a medium for the advertisement of innovations or new processes, although everything in the way of advancement most appropriately forms subject-matter for the meetings. Papers of a historical or instructive nature are usually preferred in print, as they can be studied at home at leisure; and it is not worth while to incur the expenses and loss of time attendant upon a journey of 50 miles or more merely for the sake of hearing papers read which will afterwards be published. So the chief attraction in the proceedings must necessarily centre round the discussions, though it occasionally happens that a member is in a position to contribute an interesting paper, usually bearing on some little "wrinkle" that he has originated, and which does not admit of, or call for discussion. A paper of this nature may appropriately be called a "communication;" and there is a very general disposition to regard the papers read at District Association meetings as communications, rather than as the openings of discussions. So much is this the case that even the substitution of the term "Mr. will open a discussion" in place of the well-worn "Mr. will read a paper" in the programme has proved to be of but little avail in removing it. Yet it is generally recognized that the object of a paper is the commencement of a discussion. The very common intimation in the opening of a paper to the effect that a good discussion is hoped for, and is likely to prove of greater value than the paper itself, is more of an honest statement of opinion than a conventional expression of modesty.

Although the prominent place occupied by "the discussion" is generally admitted, it is very seldom that a really good discussion takes place. In a meeting of about, perhaps, 50 members, the number of speakers, even on every-day subjects to gas engineers, will frequently not exceed half-a-dozen. Let us refer to the proceedings of The Gas Institute, and speculate upon how often the number of speakers in a discussion exceeds (say) 5 per cent. of the number present. Pursuing the subject further, it will be found that there are very few "speakers" in gas engineering circles. Those who habitually take part in discussions belonging to more than one, or perhaps more than two Associations; and therefore contribute to several discussions, perhaps a dozen or so, in the course of the year. So that if we take out the names of speakers, and compare them with the number of names on the members' lists, it will be found that a very large proportion of the whole are literally silent members, and the gas circles generally are indebted to an exceedingly small body—numerically speaking—for the maintenance of the discussions at our several District Association meetings. The reason of this is not very far to seek. The nature of the occupations and habits of life followed by gas engineers are not such as are likely to develop freedom of speech in public. Yet it is impossible not to regret the loss of much useful information, and of increased interest to the proceedings, that is caused by this general reticence. I would say to those silent members, who really appreciate the value of District Associations and the work done by them, that one of the best things they can do to further their growth and prosperity is to make a determined effort to come out of their shells, and take part in the discussions. Look over the proceedings beforehand, and make a few notes bearing upon any items of interest that may occur to you, in connection with the various subjects that have come within the range of your experience. A set speech is not expected. Only a few plain statements, preferably of facts. Which is the most interesting, half-an-hour's speech from a windy member, or the same period of time divided amongst ten speakers, averaging three minutes each?

A very prevalent drawback in the discussions is a lack of freedom. Members who are known to have an intimate acquaintance with the subject under debate, on being subsequently questioned as to the reason of their silence, confess that their experiences do not support the views set forth in the paper; and they do not wish to take up an aggressive attitude. The reader is a friend of theirs;

and they seem to labour under the belief that anything in the way of adverse criticism will in some way detract from the prestige attaching to the paper. But this is a mistake. The reader of the paper would certainly not wish to limit legitimate discussion; and if the experiences of each gas manager ought to agree on all points, where is the use of these Associations. Yet it often happens that a large portion of the so-called discussions consists of vapid compliments to the author of the paper. The more freedom about the discussions the better, provided, of course, that the personal element is left out. Personalities are not wholesome for the Association, notwithstanding the fact that they are by far the most efficient means of drawing a good attendance. Let it be known that a determined and eloquent attack is to be made upon someone or other, and the room is sure to be crowded; and this without any prominent notice of the fact upon the *agenda* paper.

Another benefit supposed to be afforded by these Associations is that of obtaining aid in difficult matters. It has always been a favourite idea with promoters that any member who is troubled with a knotty point in the course of his every-day practice should be able to submit the same at the next meeting, and receive useful information thereon. This is scarcely ever applied in England, though it finds great favour in the States, where the "question-box" is an important feature at each meeting. A member sends his question written to the Secretary; and at some convenient period, usually after the papers have been read and discussed, the President takes the list of questions submitted, and puts them to the meeting *seriatim*. If he is aware that any particular member is specially familiar with the subject under consideration, he calls upon him for a reply. But it is as difficult in England to get anything for the question-box as it is to promote *impromptu* discussion, should an unexpected hitch in the proceedings leave a portion of time in the meeting to be filled up somehow or other.

The responsibility of providing a programme or *agenda* that will occupy the whole time allotted for the meeting in the most profitable manner possible, devolves upon the Committee of Management. This is usually compiled and issued to the members in advance, and is of considerable importance, as the *agenda* is taken in a sense as a forecast of the quality of the proceedings, and as such influences the attendance. The more promising the items, the greater the inducement to put in an appearance at the meetings. Consequently, the proceedings must follow a set form and order. Free conversational discussions and absence of formality are very good things in the abstract, but the members look for the *agenda* paper; and this, of course, controls the order of proceedings in some degree, and occasionally necessitates the application of the "closure" from the presidential chair.

A great deal might be said as to the form of paper most likely to "take" at a District Association meeting. Anything in the way of a communication is limited only by the importance of, or interest attaching to the subject dealt with; but a paper put forth in the hope of arousing a discussion must, in order to be successful, follow more definite lines. It will be sufficient, in order to illustrate this point, to take a copy of the last issue of the "Proceedings of District Associations," select any paper that aroused a fair average discussion, and then underline or otherwise mark each paragraph or sentence that came for notice. We should find that the opening historical *résumé* had better be conspicuous by its absence. If admitted at all, it should be very brief. Then there need be no attempt at exhaustiveness. A fragmentary character is no drawback at all, provided the facts are plainly set forth. Indeed, any attempt to raise the paper to the level of a finished literary production will usually tend to tire and bewilder the listeners, on account of unnecessary diffusiveness. Ornaments of composition, finished and rounded paragraphs, and other things that are looked for in a review or a magazine article, are out of place in a paper intended to be listened to rather than to be read. Many papers err in attempting to cover too much ground. One or two points, concisely but clearly set forth, are more likely to attract attention than a large number of suggestions thrown out broadcast in the hope that one or two of them will take root and bring forth a good discussion. Diagrams or tables are a great help in discussions. They are usually fixed before the commencement of the meeting; and therefore receive attention at odd moments before the paper is read. But in this item, as in the matter of the paper, care should be taken to avoid overloading. While a good discussion is looked for, it must be remembered that anything like a long one is rarely desired.

I regard it as essential, either that the paper should indicate the tone of the discussion, or else that the President or the first speaker should undertake this office as soon as the paper is read. A good practical paper often falls flat on the meeting, simply because the audience do not clearly understand the points they are called upon to discuss. An awkward silence follows, only broken by a simple inquiry, or a few commonplace remarks, thrown in to the gap by somebody, in response to a request from the Chairman. On the other hand, it will often be seen that a discussion will be aroused, after an obviously deficient paper, by a few skilfully put remarks from the chair or from an experienced speaker. The line of thought taken up by the first two or three speakers will often determine the extent and direction of a discussion with greater force than the paper itself; so it is a good plan to get one or two members ready primed to follow on briskly immediately after the paper is read. Yet after every precaution, it is extremely difficult to forecast the length or character of a discussion. In the first place, the gentleman best qualified to take part may happen to be unavoidably absent. But with everybody present, the sense or pulse of the

meeting varies from minute to minute; and it does not follow that, because a paper is passed over with scant notice, it is necessarily deficient in some way or other. On account of some inexplicable reason, it may not suit the passing humour. The meeting may be heavy, dull, sleepy, over-exhausted by the previous topic, or expectative and reserving of force in anticipation of something that is to follow. So those who find that their efforts to promote a discussion are practically a failure may appropriately take comfort in the fact that it by no means follows that the best papers lead to the best discussions.

So far it has been assumed that the object in view, on the part of each member, is that of assisting in the proceedings at the meetings. But now we have to face the fact that a good number, perhaps one-half of the whole, or more, are not sufficiently interested, or do not feel themselves competent either to contribute papers or to take part in the discussions. This leads to another point—viz., that these Associations are hampered by two growths of a parasitical character, which, unless kept under proper control, are liable to sap the vitals of the whole. These I will call the recreative element and the trading element respectively. As regards the first-named, it must be admitted that the proverb "All work and no play" applies with great force to Gas Managers' Associations. The act of attending the meeting, and possibly taking a journey over new ground for the purpose, is of itself a pleasing recreation—a break in the monotonous round of duty which is the usual lot of the gas engineer. Then the gathering affords an opportunity, which does not occur in many cases at any other time, of meeting kindred spirits, and enjoying the congenial society of "brother chips." Therefore the social and the recreative elements should be allowed a fit and proper place in the affairs of the Association. Yet it must be remembered that these things always show a tendency to encroach. It is such a simple matter to adjourn the meeting half-an-hour before time, in order to enable a visit to be paid to a place of interest in the neighbourhood. Perhaps a paper must be postponed in consequence, or taken as read. Well, it will appear in the proceedings, or there will be plenty of time to take it at the next meeting. Or perhaps a little bit of sophistry to the effect that the members will be better able to deal with it at the succeeding meeting is brought in. Unless kept in check, the recreative element may get the upper hand, and cause the real objects of the Association to be obscured and lost sight of.

As to the second "parasite," the District Associations proper have very wisely exercised considerable vigilance in keeping traders out of their members' lists. I say "District Associations proper," because I regard The Gas Institute as being practically analogous in constitution to a District Association. Notwithstanding its change of name, it remains to all intents and purposes an Association of Managers. This class remains its chief support; and the aid extended to it from other sources is too evanescent to be of much real good. Incidentally it has been able, by the medium of the influential names included in its list of members, to render useful aid to the gas industry at large; but the main object and interest continues, as in the District Associations, to centre round the proceedings at the meetings. It grows, if one may use the expression, upon the same kinds of food as are conducive to the development and welfare of the District Associations, and conditions that prove disadvantageous in the one case are found to be so in the other. The heads of firms of structural engineers and contractors, who undertake the erection of gas-works complete, would no doubt derive great assistance and benefit from the proceedings; but manufacturers of tools, wrought-iron pipes, meters and gas-fittings, vendors of coals, oxide, paint, and other commodities required at the gas-works, cannot be interested in them in any other than a general way. The District Association is, to them, an indirect advertising medium; and their object in attending the meetings—and I do not say it is not a legitimate one—is the pursuit of business. The presence of the trading element to any considerable extent, simply means that a considerable portion of the time nominally devoted to the proceedings and interests of the Association, will be occupied in other ways. The member who expects to include two or three business interviews of a more or less important character in the same day's work with the Association meeting, is neither likely to derive much benefit himself—that is, of the kind that his membership is supposed to afford—nor to assist the progress of the Association. The proceedings will be disturbed by the continuous exit of those who have not time to sit out the meeting, and the entrance of others who could not manage to be present at the commencement.

No doubt there are many members whose engagements and circumstances prevent them from taking an active part in the meetings; but there are others who merely join from a hazy sort of notion that the Association is a good thing, and ought to be kept up, or because the periodical outing to attend the meeting is an agreeable change, or possibly because they regard the matter in a business sense, and find the Association a means of combining business with pleasure. Whatever the reason, they are, of course, gladly welcomed; as their countenance and subscription assist in the support of the Association. But unless there is an inner circle who take higher views than this, and are willing to do what they can in the way of contributing papers, joining in the discussions, inducing others to attend the meetings, &c., no Association can hope to go on and prosper. I have for some time observed that views of this nature appear to present themselves to those who pass the presidential chair. Looking round upon our Associations, it will be found that the Past-Presidents are always much to the fore in reading papers, joining in discussions, &c. Another reason

for this is that the presidential chair is a sure cure for natural timidity and reticence. Having once been compelled to brace up courage to take the awful plunge and address the meeting, there is quite an "at home" feeling in doing so afterwards. I am inclined to think that natural timidity is a greater drawback than one would suppose, and that if it were possible to hit upon some plan, by virtue of which every new member would be compelled to address the meeting, impromptu, for five minutes, repeating the process at each gathering until it was found that he could do so with perfect comfort to himself, a great impetus would be afforded to the discussion department.

There are several questions connected with District Associations that are purely of a local nature; and therefore cannot be treated of in a general way. The geographical circumstances, and means of travelling will, of course, affect the attendance at the meetings. Some districts are fortunate in possessing one or more good centres, easy of access from all parts, others are not so fortunate in this respect. The area of the district is also a matter of importance. It may be 300 or 400 square miles; and it may be ten or twenty times as much. All these things have to be considered in fixing upon the periods between each meeting, the time and length of the meetings, &c.

THE GUIDE-FRAMING OF GASHOLDERS.

FOURTH ARTICLE (concluded).

In finishing this series of articles, it is the author's intention to briefly refer to the class of

INDEPENDENT COLUMN GASHOLDERS.

Example I.

We will take a treble-lift gasholder having cast-iron columns 3 feet diameter, and three tiers of wrought-iron trellis girders, braced with light-ties, all of best workmanship and design, and subject to ordinary inland wind pressure

$$D = 150. \quad d = 105. \quad N = 18.$$

Now, to apply the formula $\frac{D \times d^2}{N \times C}$, we must first determine C. (See rules in present article.)

For three lifts and three tiers girders =	300
Add one-fifth for diagonal ties =	60
Add stiffness of cups, &c., one-tenth =	30
	<hr/>
	390

Deduct for shallow girders unbracketed, one-fifth	60
	<hr/>
	330 = C.

The bending moment is therefore,

$$\frac{150 \times 105 \times 105}{18 \times 330} = 278 \text{ foot-tons.}$$

The moment of resistance of a cast-iron column 3 feet diameter, $1\frac{3}{8}$ inch thick, by the rule

$$\frac{A d}{1.6} = \frac{150 \times 3}{1.6} = 281 \text{ foot-tons.}$$

which is practically what is required. But to allow for inaccuracies in casting, contraction strains, &c., it would be as well to make them (say) $1\frac{1}{2}$ inches thick at the base.

Example II.

If the same size gasholder as the last be constructed with 18 wrought-iron framed standards (I shape), instead of cast-iron columns, C in the formula must be reduced to 300, to allow for the flexibility of the standard sideways, &c. This will increase the bending moment to 306 foot-tons. Now, supposing the standard to be 5 feet deep from back to front, we have $\frac{3}{8}$ " = (say) 61 tons strain on one flange, which, at 5 tons per square inch, gives at least 12 square inches required. This may be met by a 12-inch by $\frac{3}{4}$ -inch table plate, and two angle-irons 4-inch by 4-inch by $\frac{3}{8}$ -inch, which together would give, after deducting rivet-holes, &c., about 12 square inches effective area.

NOTE.—The only objection to I shape standards is that they lack lateral stiffness. Diagonal bracing should, therefore, be adopted; and either the distance from tier to tier of the girders should not be too great, or the bracing between the standards should be double. Standards should also be strutted to the girders horizontally.

T-shaped standards are much in favour, because they are very stiff sideways. The front member does its share of the work, and relieves the diagonal ties of much strain. In fact, the standard becomes a double one, so to speak. It offers resistance both radially and tangentially; and in determining R, the resistance of the two members, both front and back, must be added together. But in doing so, only half of the theoretical resistance of the front member should be taken as effective.

CONCLUSIONS.

Having now given the method of determining the strength, or, in other words, the stability of a gasholder, and illustrated it fully by examples, we are in a position to answer for the safety of any existing structure, or, on the other hand, to design any gasholder having one or several lifts, with either partial or complete guide-framing.

The height to which the guide-frame must extend, we find does not depend upon considerations affecting the guide-framing itself; but it is limited rather by the bell or floating part of the holder.

We find that, as regards the guide-framing itself, it might very well stop short at the outer lift of any gasholder, no matter what size or how many lifts, because, when we leave out of consideration the help it receives from the stiffness of the curbs, cups, &c., of

the bell, the strain on the guide-framing is the same *theoretically* as it would be if the frame extended to the full height of the gas-holder. Practically, however, there is more liability to distortion; and consequently the rules given in the third article made provision for this. We may conclude that, as far as strength is concerned, it is not the guide-framing itself that draws the line for the reduction of its height; but it is the holder or bell working within it which decides the question.

As demonstrated in the second article, when treating of the bell, it is not safe to have more than one lift free in a three-lift holder, unless the curbs, cups, and sheeting are made abnormally heavy, to meet the severe racking strains, let alone the flexibility of the structure.

But apart from the question of mere strength and safety, there is that of expediency. Although we have determined that it is quite possible, under certain conditions, to reduce the height of the guide-framing as much as two lifts out of three, yet we must still ask, Is it practicable or workable? and, Will it pay?

The following are amongst the most serious objections:—

1. The extra weight of iron required both in the bell and the guide-framing would in all probability exceed the weight of the part of guide-framing done away with.
2. It is taking away weight from the still, stable guide-framing, and throwing it into the moving and working part of the holder. The delicately-adjusted light series of cylinders are then called upon to resist all the strains; and must therefore be converted into a heavy, stiff, framed girder, trussed wherever needed to make up for the abolition of external support.
3. The increased weight of the floating holder will give much greater back pressure upon the exhauster—a constant expense.
4. Racking and twisting strains are brought to bear upon the holder which it never suffers when the guide-frame reaches to the full height.
5. There is also much extra strain on all rollers, axles, and working parts, detrimental to its free easy working, and increasing the wear and tear.
6. The top curb must resist all distorting strains without assistance from the guide-framing, and *vice versa*.
7. Perfect adjustment of rollers, both inside and out, is an essential condition; and they must be maintained hard against the guides. This not only means extra trouble and expense periodically; but if neglected, it endangers the whole structure, and this means so much more anxiety for the manager of the works. In the old style of gas-holders, an inch or two of play would not be so dangerous as $\frac{1}{8}$ inch would in the new.
8. The thrust of rollers against the guides in the outer lift would be very great; necessitating stronger guides, rollers, &c., and outside rollers on the outer lift.
9. A gasholder having guide-framing the full height is much more handsome in appearance.

Many of the objections stated against the reduction of guide-framing by two lifts apply (although in a less degree) to its reduction by one lift. There would be no danger, however, if constructed properly; and it is a matter of calculation only as regards economy. The curbs, cups, sheeting, axles, carriages, &c., being increased and stiffened to suit, are set against the saving (if any) in the guide-framing, and possibly less labour in erection. The workmanship and erection must be very carefully watched, as so much depends upon perfect adjustment of all the parts.

In any case there would appear very little advantage to be gained by reducing the guide-framing; because the extra risk and anxiety, and constant costly examination necessary, would counter-balance much of the possible economy in the first instance.

To sum up then—

1. Each lift in any holder must exceed one-seventh of the diameter in depth.
2. It is not possible to make a reliable, healthy, and cheap, holder of three lifts, with two of them 'free.'
3. It is possible to make a three-lift holder with one lift free, and it may be cheaper; yet we find there are many drawbacks.
4. Gas-holders with guide-framing of less height than that of the outer lift (fig. 40) do not bear consideration in the light of the principles set forth in these articles. They must, therefore, be struck out of the category of practical engineering altogether.

Fig. 40.

Fig. 41.

The following should be particularly noted:—If it were not for the buckling and distorting tendency of the gasholder and its framing, the columns or standards could be made very light

indeed—in fact, the sectional area of each would only need to be a few square inches; and as far as strength goes, it would be immaterial whether we made the guide-framing a simple cylinder of sheet iron, very thin, or divided the cylinder up into posts (standards) and connected these posts together with bracing of sufficient strength to make up for the absence of the thin sheet-iron web. The more we approximate to the merely theoretical requirements, the nearer we approach the simple thin cylinder, which, if we made the gasholder several hundred feet diameter, would answer the requirements of the ordinary formula for strength of cylindrical cantilever, if made the thickness of drawing paper! Of course, if it were not absurd from a practical point of view to act upon this, we should then have but little need of guide-framing at all—provided absolutely perfect workmanship and exact fit could be relied upon—because the gasholder bell itself would be excessively strong for the purpose, and a few feet of guide-frame, just to hold it in position, would be all that would be required. (See fig. 40) But we all know such a thing would not—to put it mildly—be very good engineering; and for one simple reason. No allowance is made for the buckling and distorting tendencies; and in all, especially in large structures, this becomes a very important item. It has been treated as such in these articles.

It may be asked, Why cannot the floating holder itself be so stiffened up internally and externally with vertical stays, strong girder rings, ties, &c., as to make external support (beyond a few feet at the base) unnecessary? As far as mere theoretical strength is concerned, it *could* be so; but it would be very impracticable for many reasons.

1. Because of the excessive weight to be thrown into the holder. It is, in fact, putting the weight of the usual external guide-framing into the framework of the holder, in order to resist distortion, &c.
2. The material is not so well disposed; having no base to stand upon.
3. The elasticity and variation in length of iron, &c.—leaving out other reasons—make it *impossible* to attain the absolutely necessary conditions of *perfect fit* and *perfect rigidity*.

These are only a few of many reasons, which have already been advanced in former articles against such a proposal.

It is perhaps necessary to remark that, although the force of wind to which a structure may be exposed cannot be given exactly, yet this does not affect in any way what we have done. All the doubt which may be expressed concerning the wind pressure acting on a gasholder is equally applicable to the wind pressure on a bridge, or any other large and exposed structure. The force of wind has to be met in both cases; but on that account we need not assume that it is impossible to determine the strains on either the one or the other. All we have to do is to determine the strains due to what we consider the maximum uniform wind pressure that is ever likely to come upon it. This may be 20, 30, or 40 lbs., whichever we please; it makes no difference to the method. In our case we have taken about 30 lbs. as the maximum, and constructed all the formulae accordingly; and, of course, if the structure defies the maximum, we need not trouble ourselves about the lesser strains—they are covered by it. It is a very simple matter to modify the formulae to suit any desired wind pressure.

In conclusion it has been the author's endeavour to accomplish the following:—

1. To show, in the simplest possible manner the principles relating to strength of gasholders, and the manner in which they are affected by varying the design.
2. To give ready rules for determining the strains on the guide-framing for gasholders under different conditions; also the floating holder, as far as it is affected by alteration in the guide-framing.
3. To show the extent to which the present guide-framing can be modified as regards height; and the advantage or disadvantage likely to result from such practice.

*** Note on Mr. Gadd's Gasholder.*—It is, of course, evident that the method of determining the strains demonstrated in these articles, refers to gasholders having *vertical* guides. Since these papers were written Mr. Gadd has proposed to construct gasholders with *inclined* guides. This is a radical departure from all previous practice, and involves a somewhat different method of treatment; it being asserted that, with inclined guides, the base of the holder will always be maintained in a horizontal position and may be considered as "fixed."

We have received from the Secretary of the Institution of Civil Engineers (Mr. J. Forrest) a list of the subjects suggested for original communications to be read and discussed at the ordinary meetings of the Institution in the forthcoming session. Among them are the following, in which our readers are specially interested:—"The Best Combined System of Warming, Ventilating, and Lighting Large Buildings." "Central Station Electric Lighting." "The Sale of Water by Measure." "The Effect of Wind upon Structures, as influenced by (1) their Superficial Area, (2) the Form or Position of the Exposed Surfaces, (3) the Shelter of Adjacent Bodies, and (4) the Dynamic Action of Sudden Gusts." "The Petroleum Engine and its Applications." "The Application of Electricity to the Purification of Water and Sewage." For approved papers, the Council of the Institution award premiums, arising out of special funds bequeathed for the purpose.

Technical Record.

NORTH OF ENGLAND GAS MANAGERS' ASSOCIATION.

The Twenty-third Half-Yearly Meeting of this Association was held last Friday, in the Offices of the West Hartlepool Gas and Water Company. The PRESIDENT (Mr. T. Bower, Engineer of the Company) occupied the chair; and there was a good attendance of members and friends.

The HONORARY SECRETARY (Mr. W. Hardie, of Newcastle-upon-Tyne) having opened the proceedings by reading the notice convening the meeting,

Mr. FISHER, the Chairman of the Hartlepool Gas and Water Company, said he would not detain the members long; but he craved their indulgence for a few minutes in order that he might say a word or two. On behalf of the Company, he had very great pleasure in according to them a cordial and hearty welcome. He remembered their last visit to the town, which, he supposed, was about seven years ago. Many changes had taken place since then. Old faces had passed away; and new ones appeared among the members. On the occasion of their previous visit, they selected for their President their much respected and esteemed friend Mr. Trew-hitt, the Secretary; and there was associated with him one who had passed away—his lamented friend Mr. Mossman, the Engineer. He was very pleased to find that they had this year done honour to their Engineer (Mr. T. Bower), by selecting him as their President. Mr. Bower was one who, although comparatively new to the district, had already won golden opinions. West Hartlepool had made considerable progress during the last seven years. Many of those who were there before would have noticed that the town had very much extended, and that the gas-works were also a great deal larger. The two were very much bound up with each other. Prosperity to the town meant prosperity to the Company; and *vice versa*. The town was restricted on the north-east; but on the south and west it had extended very much. It had also improved its standing. They had now attained the dignity of a borough and a Corporation. Their first Mayor—a Jubilee Mayor—was now presiding over the town. They would probably not have an opportunity of meeting with him; but he was sure the Mayor would have extended to them on behalf of the town, as he (Mr. Fisher) did on behalf of the Company, a very hearty welcome. He thanked them again for choosing West Hartlepool as their meeting place.

NEW MEMBERS.

The following gentlemen were admitted to the Association:—As Members: Mr. Herbert Lees, of the Workington Gas-Works; and Mr. E. W. Smith, of the Cockermouth Gas-Works. As Associates: Mr. W. Frazer, of Messrs. Frazer and Son, Newcastle; and Mr. E. F. Wallace, of the Trindon Colliery.

The PRESIDENT then delivered the following

INAUGURAL ADDRESS.

Gentlemen,—I thank you most heartily for the honour you did me, at your last meeting, in electing me your President for the ensuing year. I have some doubts as to being able to fulfil the duties of the office in the manner they demand; and, while fully sensible of the great compliment you have paid me in placing me in this position, I am also deeply impressed with the duties and responsibilities of the office, following as I do the worthy men who have occupied this chair before me. I shall, however, endeavour, with your assistance, to carry out the objects of our Association; and I trust that, if we are not able at the expiration of my term of office to report much progress, we may at least have witnessed no retrogression. I trust, too, that each member will avail himself of that interchange of opinion and practical knowledge which is a chief feature of our meetings, by bringing forward, either by means of a paper or discussion, any subject that may be of interest to the members, or of service in the further development of the business with which we are all associated. I would especially ask this of the younger members of our profession, who will find that they are not only benefiting their fellow-members by imparting to them their experience, but that they themselves obtain much information in the discussion arising thereon that could not possibly be procured by a position of isolation.

We may fairly congratulate ourselves on the progress of the gas industry during the past year. Increased consumption has taken place in most towns throughout the country; and this fact is all the more encouraging when we consider the number of rivals which gas has to face, and the great competition that now exists both in public and private lighting. I am of opinion that the present year will be even more prosperous than the past; and so far as the North of England is concerned, I believe we are entering upon a term of trade prosperity, when considerably more gas will be required both for domestic and commercial purposes. Although the gas undertakings in charge of the members of this Association at present represent a capital of nearly five millions sterling, making 7200 million cubic feet of gas, and using over 710,000 tons of coal annually, I have no doubt that, as a greater demand arises, the necessary capital to meet it will be readily provided by the public, in whose favour gas stock seems to become more popular year by year as an investment.

Of late years much has been said of the electric light as a competitor with gas. I do not now intend to say much on this matter, further than this—that I think any diminished consumption of gas due to the introduction of such light has been fully compensated for by the increased consumption that has taken place through the public now having a desire for more light than they had prior to

the introduction of the electric light; and while admitting that there are special purposes for which the latter may be more suitable than gas, I feel sure that, for general lighting, gas has yet a bright future, and will long maintain the premier position it now holds. While, however, putting aside any fear of diminished gas consumption through the introduction of the electric light, I am not at all insensible to the fact that in paraffin oil we have a competitor that is likely to some extent to interfere with increased consumption. More especially will this be the case in small towns, and towns where the population is of a migratory character. I feel convinced that, unless the greatest facilities be given to the working classes to encourage the consumption of gas, that the use of oil, should it remain at its present value, will still further extend. And not only for domestic lighting will this be the case, but also for manufactories—such as iron, engineering, shipbuilding, and other large works, where of late the Lucigen light has been much used; it having in many instances in the North of England been substituted both for gas and the electric light. I think, however, that a great deal of the increased lighting by oil is due solely to the very low price of this commodity—a state of things resulting from the recent discoveries of such enormous and almost unlimited quantities of oil, the better facilities for its shipment to this country by the adoption of special tank steamers in preference to the usual system of shipping by barrels, and the keen competition that has arisen between the Russian and American petroleum districts. But although its cost is so very low, the disadvantages and risks attending its use are, as you know, very great; and almost every day this fact is prominently brought before us by the frequent occurrence of deaths from burning caused by the upsetting of petroleum lamps. There is besides the constant trimming of such lamps, the breaking of chimneys, &c. (which is a very great annoyance compared to the simple turning of the ever-ready gas-tap), to say nothing of the constant obnoxious smell arising from its use. All these points considered, I am of opinion that, if gas companies still continue to supply gas at the lowest possible price, diffuse a knowledge amongst the public of the conditions under which gas may best be consumed, and offer every inducement for its economical consumption, even the competition from cheap oil may be overcome, and the day is far distant when gas lighting will be materially affected by any of its competitors.

For purposes of cooking, heating, and motive power, much may yet be done to extend the use of gas; and we ought not to rest content until we can report that our customers for these purposes are quite as numerous as those for lighting. I look forward with hope that the day is not far distant when, not only cooking and heating stoves will be established things in all well-regulated households, but that small gas motors will become general, both for domestic and trade requirements, and that the consumption of gas for such purposes will become as great, if not greater than that for lighting. Without, however, waiting for such uses of gas to develop itself in the course of events, gas companies should provide all possible facilities that will tend to urge on its speedy introduction; let the public know and see the advantages to be gained by using gas for these purposes, and provide apparatus of the best kind either on hire or purchase. Especially would I recommend the hire system as one that ought to be adopted by all companies and corporations who have not yet introduced it; and should it still be necessary to advance any argument in favour of taking this step, I would point to the great success that has attended its introduction in almost every case—our own being no exception to this rule. Some sixteen months ago an exhibition of gas apparatus was held; and since then upwards of 300 stoves of all descriptions have been fixed—resulting in an increase to our business for this purpose alone of something like 6 or 7 per cent. on our total make of last year.

In the introduction of gas-engines, I am not sure that gas companies themselves have done all they might to extend their use; for, notwithstanding the fact that in the smaller sizes they have been proved both convenient and economical, we find in many gas-works that steam is still employed in preference to gas. This ought not to be the case, as the public very justly look to us for example. Gas-engines are, however, daily becoming more popular; and there are now some 28,000 of the "Otto" type alone in use. In several towns as many as one per 1000 of the population is in use; and when the advantage in the saving of boiler space, attendant's wages, diminished nuisance from smoke, and all the minor nuisances from steam, are considered, these alone are points of sufficient importance to recommend their employment. But even in the working cost, gas-engines with a consumption for many purposes not exceeding 20 to 25 cubic feet of gas per indicated horse power per hour will be found more economical than the cost of working many steam-engines, some of which were found by Sir Frederick Bramwell, in his recent tests at Birmingham, to be consuming as high as 20 lbs. of coal per indicated horse power per hour. I know this is a very high estimate, compared with the splendid results that have been attained by many noted makers of modern steam-engines on a large scale. But in small engines of more recent make, and such as are used for light trade purposes, it is no unfrequent occurrence to find the consumption of coal per horse power even much in excess of what I have already stated; and in these cases, in addition to the convenience before mentioned, gas-engines will be found a very economical substitute for steam.

Although the fall in the value of residual products during the past few years has been so rapid, and resulted in greatly diminished revenues to gas companies from this source, it is, from a consumer's point of view, matter for congratulation, that, in very few cases

indeed, have companies thought it necessary to increase the price of gas; such reduced receipts having been met either by the gas companies drawing upon their reserve fund, where any existed, or being content where none did exist to declare smaller dividends. This is a point that ought not to be overlooked by the public, should the value of residual products so far recover as to admit of better dividends.

Throughout the past year the value of tar and its products have shown considerable improvement, and will, I believe, still continue in an upward direction. Quite recently an offer was made to one of the largest chemical manufacturing firms in the kingdom to purchase the whole of the tar products produced at their works during the year 1889 at present market prices; and although there may be an element of speculation in such an offer, yet to some extent it indicates that the parties most intimately connected with the business have confidence in existing prices being maintained. I trust, however, that both buyers and sellers will abstain from making long forward contracts on what may seem favourable terms, as, however pleasant it may be for companies to receive for the time being prices for their tar far in excess of its market value, such a condition of things cannot tend to cultivate a healthy state of trade, as it must be equally unpleasant, as well as disastrous, to chemical manufacturers to have to pay for tar a price far in excess of what its products will realize.

Sulphate of ammonia, which commenced the year at £12 10s. per ton, has continued to average a little under that price down to last weeks' quotation of £11 10s. per ton; and at this figure the market is very firm. As the manufacture of sulphate becomes more general among gas companies, I should anticipate that a greater demand for it will arise, as each company will, I feel sure, use all possible means of bringing before farmers, in their own immediate district, the value of sulphate of ammonia as a fertilizing agent, and thereby create a better local demand. Farmers, too, in these days of better technical and scientific education, should not be slow to avail themselves of such facilities, as in purchasing sulphate direct from the producers they will be far more likely to get full value for their money than by purchasing in the open market manures that are not always free from deleterious substances, and in very many cases do not contain the proportion of ammonia stated by agents anxious to effect sales; whereas, on the other hand, gas companies will desire to secure local reputation and will at least see that the farmer gets what he bargains for.

Plant for working on the continuous, in preference to the intermittent system is now being generally adopted, as tending not only to reduce the cost of producing sulphate, but also to deal with much larger quantities of ammoniacal liquor in a given time. The elimination of the sulphur from the waste gases arising from such manufacture has of late received much attention, with the result that the Claus patent sulphur recovery plant is becoming much more used. This, I think, is a step in the right direction, as, even if the plant is not found very profitable, it will convert into a commercial commodity what has hitherto caused more or less nuisance. On this ground alone, it is worth our consideration; as every effort should be used to carry on our business with as little annoyance to others as possible. Later on you will have an opportunity of seeing a new sulphate plant, on the continuous process, recently put down for my Company by Messrs. R. and J. Dempster, and in conjunction therewith one of the Claus sulphur recovery plants erected by Messrs. C. and W. Walker. In consequence of the short period they have been at work I am unable now to give many particulars of the cost of working, but may at some future time have the pleasure of placing before you the results of a more lengthened experience.

The demand for gas coke has of late been very brisk, resulting in most of the old stocks being cleared out, and better prices realized. This demand I attribute partly to a revival in the home trade, causing a larger consumption, and partly to the increased quantity that has recently been sought after for export. Both for domestic and trade purposes, coke ought to be much more extensively used, were its advantages thoroughly understood and appreciated by the public. It is not generally known, I believe, by the owners of small steam-boilers that, by the use of coke under such boilers, steam can be raised quicker than by coal, and in many cases at much less cost. For smiths' purposes, too, it has been found very serviceable, and in a large number of shops is now almost exclusively used in place of coal. The extended use of coke would also tend to assist in solving the vexed question of smoke abatement, and reduce the enormous loss resulting from the dense volumes of smoke which now issue from the chimney stack, besides clearing the atmosphere of such smoke, and thereby assisting to make life more pleasant in our populous towns.

A movement has recently been started in the north by the Worshipful Company of Plumbers, to establish local centres for the registration of plumbers. This is a movement which should in all towns receive the hearty co-operation and support of all gas managers and gas companies. It is unnecessary for me here to dilate upon the many annoyances that gas consumers have to put up with through defective plumbing; and any steps that will tend to place plumbers' work on a more scientific basis will, I feel confident, be accepted as a great boon by the general public, who must necessarily have greater confidence in the work executed by registered plumbers, who are known to be men of ability for their work, than in the work done by indifferent workmen who are not registered. To plumbers themselves, this system will be very advantageous, as it will ensure competent men only being sent out to first-class work at better wages; thus giving to those who have served a

proper apprenticeship, and who, by careful attention to their work, have thoroughly mastered the details thereof, better remuneration for their labour than the careless and indifferent workmen whose labour in this particular branch is too often found to be dear at any price.

I am afraid, however, that many of the annoyances gas consumers have to contend with are not due altogether to careless plumbing, but in many cases may be traced to consumers themselves, who will persist in purchasing the cheapest of everything they can find connected with gas-lighting—articles that in the end often cost very much more than those of a better class, to say nothing of the constant annoyance arising from the use of such fittings. One of the aims of the Plumbers' Company is to endeavour, in the erection of new houses, to prevail upon the builders and architects thereof to omit the plumbing work altogether from their specifications, and to set apart such a sum as will enable this to be done in a satisfactory manner by registered plumbers, at such rates as may be found remunerative for better class work; thereby avoiding to some extent the great competition that now exists in plumbing, and the scamped work arising from such competition and low prices. It will be necessary in doing this that some schedule of prices shall be adopted for the different classes of work to be carried out; but it also occurs to me that, before such a system could be satisfactorily adopted, it would in the case of gas and water fittings be necessary also to have a schedule of standard sizes, which all registered plumbers must be compelled to work to; and although this system is already in existence in some towns, it must, to ensure success, and its universal adoption, be enforced by some legal and acknowledged authority, such as parliamentary power, or, failing that, instructions from a Joint Committee composed of members of the Plumbers' Company, who would have control of all registered plumbers, and members of The Gas Institute acting on behalf the gas companies throughout the country.

Referring as I have done to the necessity of standard sizes being adopted in gas-fitting, leads me for a short time to the consideration of the adoption of this system to gas plant generally—a subject which, to my mind, deserves more attention than it has hitherto received either from gas managers or the makers of gas apparatus. Some time since Mr. Whyte, of Seaham Harbour, brought this matter before our Association. Although in his paper he dealt chiefly with retorts, I am of opinion that the principle may be extended to most apparatus connected with gas-works with very considerable advantage to both makers and users of such; and I feel quite sure that this fact will be admitted by all who know the great benefit arising from the adoption of Whitworth standard sizes of threads, and standard sizes for meters, &c. There is perhaps no part of the apparatus employed in gas making which permits of greater scope for reform in this direction than retorts and retort-fittings. To describe all the different sizes and shapes of those in use would be a work far too tedious for this meeting, and one that I shall not attempt; but I would ask how often do we find, in works of only moderate size, three, four, or more, different sizes and shapes of retorts in use on one bench, separate patterns for all of which have had to be made—thereby incurring additional expenses, which must be borne by the users of these articles, either directly or indirectly, to say nothing of the confusion that arises through so many different patterns being in use. Take, for instance, the Δ -shape retort—a form that is very extensively used—it will be found that almost every engineer has some particular preference both in size and shape. It is surprising the number of different shapes that are in use of this form of retort of even the same size. Some have sharp square corners; others are a little round; while in other cases they are so round that it is difficult to distinguish them from ovals. Then, again, in others the top part will vary; while others differ in the number of bolt-holes. If all these shapes be made in six, eight, or as many as ten different sizes, you would readily see that the cost incurred therein must be enormous; and the matter becomes one of greater importance than we are apt to attach to it.

Many manufacturers have given it as their opinion that, were standard sizes adopted, a saving of at least 10 per cent. might be effected; while in retort-fittings almost as great a saving might also be made. And this is not the only advantage we should gain by the adoption of standard sizes. Many, if not all of us, have at one time or another suffered some inconvenience and annoyance through delay in the delivery of retorts at a time of the year when makers have been pushed to execute in a short time more orders than they were able to do; and some of us also remember having had retorts sent that had been taken from the kiln long before they were sufficiently well burned. This might to a great extent be overcome if makers knew the sizes likely to be required, and could put into stock a number of each size, which could be made at a time of the year when they had few, if any, orders in hand, to be kept until the busy season, or for cases of emergency arising from accidents or other causes, when they would be ready for despatch at once. Then for purposes of comparison of the make of gas per mouthpiece at different works, how much simpler it would be were standard sizes universal?

In the case of valves, how seldom do we find two makers having the same size of flange, or having the same centres for bolt-holes; and, again, in flange-pipes the same thing occurs, often resulting not only in extra cost for patterns, but in considerable delay to get special sizes; whereas in standard sizes they might often be kept in stock and ready for use at once. There are many other advantages I could name in favour of the system I advocate, all of which point

in one direction—viz., a considerable saving in cost, as well as the great convenience arising therefrom to both makers and users; but I think I have said sufficient to justify some steps being taken to bring about this change in gas apparatus. I am aware that many difficulties and prejudices would arise before such a change could be brought about; but I am also of opinion that, with hearty co-operation on the part of makers (which I feel sure will be readily given), all such difficulties might be overcome, and a recognized standard of sizes adopted, which, while giving sufficient scope for improvement and *bona fide* progress, would reduce the cost of apparatus, and tend to still further cheapen the cost of gas. I would suggest that the consideration of this subject is of sufficient importance to be relegated to a Special Committee, composed of members from all the District Associations, to collect information and report thereon as to the practicability or otherwise of its adoption; and I feel sure much good would result from the labours of such a Committee.

The better technical education of young men about to enter the gas profession, is a question that has of late received much attention; and some good suggestions on this subject have been offered by our older members, which will no doubt not only prove serviceable, but tend to direct more particularly the attention of young men to the great necessity for them to give this matter the most careful attention, as it must be patent to all that those who in the future combine scientific attainments with practical experience are those most likely to come to the front. The spread of scientific and technical education should lead to the introduction of new and improved appliances for both the manufacture and distribution of gas, and with it will also arise the question of how best to stimulate and encourage the use of such improved appliances. It is well known that the preliminary expenses necessary to be incurred in experimenting with new apparatus, previous to its introduction to the public, often deters the adoption and proper working out of new inventions, which might otherwise be of much value; and until some scheme of dealing with such matters—either by means of Research Committees appointed by The Gas Institute, or otherwise—is determined upon, I would strongly urge upon directors of gas companies and gas committees to allow their managers every reasonable facility and help to work out any new idea that may be likely to benefit not only themselves, but the industry generally.

The question of gasholder construction is one that is just now receiving much attention; and should the experiments recently made by Mr. Livesey still continue to prove successful, and the views of Mr. Gadd be brought into satisfactory practice, we are likely soon to witness great changes in the method of construction of this part of our apparatus, which will tend to lessen a cost that is now one of the chief factors in our capital charge. I hear, too, that our friend Mr. Ashmore, whose long experience in gasholder construction well fits him for such a duty, is perfecting some scheme with a view to this end. As we are to have a paper to-day upon gasholders, however, I will not at present say more on this subject.

In conclusion, I would add a few words with reference to the resignation of members of the Council of The Gas Institute which has taken place since our last meeting. I am forcibly reminded of what Mr. Newbigging in his address seemed to foreshadow, when presiding over the twenty-first annual meeting at Manchester—viz., that the meeting then being held might perhaps mark a crisis in its history. It would almost seem that such was to be the case; and if the Institute is to be of that service to the members in the future that it has been in the past, it will be necessary that the greatest care and judgment should be exercised in future proceedings. In Mr. Woodall, the President, we have a gentleman likely to command the confidence of a great majority of the members, whose hearty support I have no doubt will be given him in any scheme of reorganization he may submit. I would point out how desirable it is, in the vacancies that have to be filled up, that gentlemen from all parts of the kingdom should be elected, and not too many from any particular locality; as by this means the whole of the members would be brought into closer contact with the Council, through their representation thereon. I would suggest, as a step in this direction, and in order also that the District Associations may become more in touch with the Parent Association, that the President for the time being of all District Associations should be a member of the Council.

The PRESIDENT, in calling upon Mr. J. Wright, of Stockton-on-Toos, to read a paper on "Modern Methods of Increasing Gasholder Storage," said it was at his own special request that Mr. Wright had kindly consented to contribute this paper. It occurred to him that it might be desirable to have a paper on this subject, following up the remarks upon gasholder construction which they had from their President last year; and he had no doubt that Mr. Wright would place before them particulars of gasholder construction which would be interesting to them all.

Mr. WRIGHT then read his paper, as follows:—

MODERN METHODS OF INCREASING GASHOLDER STORAGE.

There cannot be two opinions among people engaged in gas manufacture or gas engineering as to the absolute necessity of finding out the cheapest and best methods, either of laying down now gas-works or carrying out extensions of old ones. More especially is this necessary when looking at the competing interests which gas meets at every turn. These interests are so palpable to everyone here present, that it is unnecessary and almost unwise to particularize them. Hence it is, Sir, that, when I received your

invitation to prepare a paper specially for this meeting, I responded with some alacrity; feeling sure that on the subject of "Modern Methods of Increasing Gasholder Storage," I could indicate a course, and supply figures which, I trust, will be of interest to those engineers who are hampered in that direction.

A modern gas-works is so much a centre of "Light and Leading" that no matter how rural a site is chosen for its location, you no sooner see it established, than the speculative builder puts in an appearance; and in a very short time, the works are closely environed by streets of houses and their usual accompaniment—a dense population; making extensions of site very costly and well-nigh impossible, owing to considerations connected with the outlay of capital.

Gasholders are a trouble to many gas managers. They take up so much space, there is so much risk in the construction of new tanks, and opinions differ so widely now as to what is or is not an absolute necessity for the construction of the gasholders both inside and outside, that it is putting it mildly to say that to the ordinary gas manufacturer, they are an unsolved problem. In a short paper of this description it is impossible to go into the *pros* and *cons* of either the old system of gasholder construction or of all the "fads" that are now bulking so largely before the gas world. It is a still greater impossibility to attempt to give any rules or descriptions of gasholders which would make them and their treatment more familiar to the average gas manager. I must, therefore, content myself with taking one specific branch of gas engineering—viz., that of doubling or trebling existing holders, and indicate what has been done to relieve pressing cases for increased storage, without having to go into questions connected with extension of site, re-arrangement of mains, &c.

It is desired to make this paper of interest and profit to all members of this Association, whether they are interested in large or small concerns; and I have therefore made the tables of dimensions and costs (Nos. 1 and 2) sufficiently extensive to meet the cases of small and large works. These are the central points of my paper, and are before you.

TABLE I.—New Holders and Tanks.

No.	Capacity Required.	Diameter of Tank.	Cost of Tank.	Cost per 1000 feet Capacity of Holder.	Diameter, Depth, and Description of Holder.	Cost of Holder.	Cost per 1000 feet Capacity.	Total of Tank and Holder.	Total Cost per 1000 feet Capacity.
	Cubic Feet.	Feet.	£	£	Feet	£	£	£	£
1	55,000	62	900	16.36	60 x 20 Single	750	13.64	1650	30.00
2	75,000	72	1200	16.00	70 x 20 "	900	12.00	2100	28.00
3	110,000	82	900	8.15	60 x 20 Two-lift	1000	9.09	1900	17.28
4	150,000	72	1200	8.00	70 x 20 "	1350	9.00	2550	17.00
5	200,000	82	1400	7.00	80 x 20 "	1900	9.50	3300	16.50
6	250,000	82	1650	6.60	80 x 25 "	2100	8.40	3750	15.00
7	300,000	92	1500	6.00	90 x 24 "	2500	8.33	4300	14.33
8	400,000	102	2250	5.62	100 x 26 "	3000	7.50	5250	13.12
9	500,000	122	2500	5.00	120 x 24 "	3500	7.00	6000	12.00
10	750,000	122	2500	3.30	120 x 24 Three-lift	5250	7.00	7750	10.30
11	1,000,000	143	3000	3.00	140 x 24 "	6500	6.50	9500	9.50

TABLE II.—Cost of Doubling or Trebling Existing Holders.

Reference Letter.	Capacity Required.	Approx. Dimensions of Holder added.	Cost of Telescoping.	Total Cost per 1000 feet gained.	Total cost per 1000 feet from Table I.	Saving per Cent.
	Cubic Feet.	Feet.	£	£	£	
A	55,000	60 x 20	650	11.80	30.00	60.75
B	75,000	70 x 20	865	11.50	28.00	59.00
C	110,000	80 x 22	1155	10.50	17.28	39.20
D	150,000	90 x 24	1250	10.00	17.00	41.18
E	200,000	100 x 27	1900	9.50	16.50	42.43
F	250,000	120 x 25	2250	9.00	15.00	40.00
G	300,000	130 x 24	2550	8.50	14.33	40.70
H	400,000	150 x 25	3200	8.00	13.12	39.00
J	500,000	150 x 30	3750	7.50	12.00	37.50
K	750,000	160 x 38	5250	7.00	10.30	32.00
L	1,000,000	180 x 40	6000	6.00	9.50	36.75

Table I. gives the average dimensions, capacities, and costs of ordinary brick or concrete tanks, together with their gasholders of ordinary construction. I do not propose to try your patience by reading through all the figures of either of the tables, but may explain that, taking case No. 1 in Table I., where it is supposed that additional storage is required for 55,000 cubic feet, this is represented by a single-lift gasholder 60 feet diameter by 20 feet deep. The diameter of the tank to contain the holder is given in the second column. The cost, exclusive of mains, in the third. Then you have in the fourth column the cost of the tank per 1000 feet of additional capacity gained. Then, in the order named, you have the dimensions of the gasholder; cost of ditto; cost per 1000 feet of storage gained; total cost of tank and holder; and in the last column the total cost for combined tank and holder per 1000 feet of storage gained, which in this case, runs out to £30 per 1000 feet. You will please observe that I have not included the cost of land or of mains in any of my figures.

I will now suppose that you have built holders and tanks on every available yard of the gas-works; and it becomes a question with you how to get 55,000 cubic feet of storage. Table II., example "A," shows what I call the cheapest way of accomplishing it—viz., by telescoping the gasholder. You have the capacity in the second column; dimension of holder in one lift to contain the gas in the third; the cost of telescoping in the fourth; and the

total cost per 1000 feet in the fifth. Then, for the purposes of comparison, I bring the figures per 1000 cubic feet from the last column in Table I., and place them alongside the cost shown by Table II. for doubling or trebling; and the last column exhibits the enormous saving of 60·75 per cent. in favour of telescoping. This may be regarded as an extreme case, and it undoubtedly is; for it may be noted that, by using a small telescopic holder, and building a much smaller tank, considerable cost may be saved. I have not gone into this question, because very small telescopic holders are troublesome, and because the difference is clearly shown lower down the table. Take, for instance, case No. 3, where the required capacity is 110,000 cubic feet. The cheapest way to obtain this by a new tank and gasholder is to build a 62 feet tank, and put in it a two-lift holder 60 feet by 20 feet. By following through the figures, you will see that the increased capacity of the gasholder reduces the cost of the tank per 1000 cubic feet to £8·13 instead of £16·36; and the total combined cost of the tank and holder is reduced to £17·28 per 1000 cubic feet. The parallel case to this in Table II. is that indicated by the letter "C." To gain a capacity of 110,000 cubic feet by telescoping would need a single-lift 80 feet diameter by 22 feet, added to an existing one. This can be done, as shown by the table, at a cost of £10·5 per 1000 cubic feet, as against £17·28, or 39·20 per cent. in favour of telescoping.

	Cubic Feet.	Per Cent.
Case D in Table II., 150,000 capacity shows a saving of		41·18
" E "	200,000	42·43
" F "	250,000	40·00
" G "	300,000	40·70
" H "	400,000	39·00
" J "	500,000	37·50
" K "	750,000	32·00
" L "	1,000,000	36·75

It ought to be added that example "C" represents the actual cost of a holder dealt with in this way. Case "F" is the average of six two-lift holders which were converted into three lifts for one Corporation. Instance "G" is an average of four holders telescoped. Case "J" also represents the actual cost of a contract executed.

If any criticisms should be offered as to my figures being too high or too low, my reply is that the costs in Table II. are estimated on the same basis as Table I.; so that the differences are in the same ratio. Therefore my deductions or percentages will be the same. The figures generally are based on the assumption that the first holders have been constructed with a view to telescoping. It is, however, to be feared that many holders have been erected without the necessity for their extension having been apparent at the time of their construction. In such cases as these, it will be necessary to put a new holder altogether inside the old one, by cutting away as much of the top sheets as is necessary, to make room for the new inner lift. This will probably increase the total cost, as given by Table II., by 10 or 15 per cent.; but my figures give sufficient margin to allow for this increase, and leave ample justification for what I will call a "telescoping policy."

I must not, and do not, desire to ignore the difficulties that lie in the way of so many gas engineers in following the policy I have described. For instance, you may have only one gasholder, and may consider it unsafe (so to speak) to have all your "eggs in one basket." To a member so circumstanced, I would say: By all means build another holder and tank before adopting the policy indicated. Another may have a guide-framing to his holder unsuitable for extension, or possibly incapable of standing as it is; and the only resource here is to dispense with the old and substitute new. Columns which are now small can be raised up and supported on stronger bottom lengths. Columns or standards that are large can be lengthened out, and braced by a system of girders and diagonal bracing. If it is inconvenient to adopt any of these ideas, we must not forget the important experiment which has been tried by Mr. George Livesey, at Rotherhithe, which points to the possibility of lengthening and increasing the capacity of gasholders without having to add to the columns or girders, where they are sufficiently strong. This will at once reduce the cost so as to make telescoping much more favourable than the figures shown in my tables.

It will, of course, be possible to effect still greater economies in telescoping gasholders, if the ideas which are now so much under consideration, of dispensing with guide-framing, are found to be practicable. As an item of interest in this connection, I may be permitted to state that my friend Mr. Ashmore, some weeks before the Doncaster meeting of the Manchester District Institution of Gas Engineers and Managers, patented an idea which will be effective without even the complication of fixing spiral guides in the tank. For obvious reasons, we cannot here go into the details of one or the other invention, as they are foreign to the subject of this paper, and are only mentioned to remind you that further developments of the science of gasholder construction may, and no doubt will, enable you to telescope holders very much below the favourable figures I have now laid before you.

Discussion.

The PRESIDENT said they must all have been interested by Mr. Wright's paper; and, apart from the interest that attached to the details which he had given, a very great point had been gained in the reading of the paper in his placing on record statistics in connection with gasholder manufacture and the working out of the cost of their construction, which were only known to manufacturers themselves. The placing of these on record would, he thought, be of very great service to gas managers who

were considering the question of increasing their storage. This was one of the main reasons why he invited Mr. Wright to read a paper upon this subject, because he felt that they had only individual cases recorded of the doubling or trebling of gasholders; whereas manufacturers like Messrs. Ashmore, Benson, Pease, and Co., who were constantly engaged on this sort of work, had details at hand which gas managers could not command, and which would be of much help. He trusted, therefore, that if any managers there were anticipating extensions, or would like to gather any information on the subject, they would not be slow to come forward in the discussion.

Mr. W. FORD (Stockton) observed that, before attempting to make any remarks upon Mr. Wright's paper, he might say that a gentleman was present who was much more accustomed to deal with actual manufacture than most of them; and he thought it would be interesting to hear what criticisms he might offer upon a paper like that, because they all knew that manufacturing firms who had leading men like Mr. Wright or Mr. Cripps, were very much more able to enter into details than ordinary gas managers, who were sometimes filled with hesitation on the subject.

The PRESIDENT remarked that he had intended to call upon Mr. Cripps, but thought it probable that a member of the Association would have spoken first.

Mr. F. S. CRIPPS (London) said he would offer a few remarks, but not by way of criticism on the paper. He agreed with Mr. Wright that, in the majority of cases, it was better to add a lift to a gasholder than erect a new one. Of course, there were circumstances which governed individual cases. They could not say: "I have a gasholder; and I will add another lift to it," without first considering whether the guide-framing was sufficiently strong, or whether, on other grounds, it was advisable to do it. He could not then go into the various things which one had to consider; but he might say that, in most instances, it was best to add a lift. He also quite agreed with Mr. Wright that, in designing a gasholder in the first place, provision should be made for telescoping in the future, either for adding a double or a treble lift as the case might be. Of course, it was very difficult, with an old-fashioned gasholder, with rickety guide-framing perhaps, to add a new lift to it, because they would be cutting through the framing, and incurring an increased expenditure, which would not have been brought about if it had been considered in the first instance. Regarding the abolition of guide-framing altogether, this was such a big subject that he could not enter upon it; besides, Mr. Wright had not advanced it in his paper. He understood, however, that the Rotherhithe gasholder was working very favourably; and it was his opinion that, in the case of gasholders where the guide-framing was sufficiently strong as it stood, and the ground lifts were very rigid, a new inner lift might be added without any danger. The Rotherhithe gasholder, they would say, proved it; but he believed a good deal of extra strengthening had to be made at the bottom before it was undertaken. He did not know that he could say anything else; but he would be very glad to answer any questions.

Mr. W. HARDIE (Newcastle-upon-Tyne) remarked that they had two gasholders at their Elswick works; and they had not room to put down another, so they telescoped the then existing ones. This was done two or three years ago; and the holders had worked very well. By telescoping these holders, they obtained extra storage at a very moderate price; but Mr. Ridley would be better able to give information about it than he was.

Mr. G. RIDLEY (Newcastle-upon-Tyne) said the telescoping of the two holders was a very great acquisition to the Company; for the simple reason that it increased the storage by one-third. Trebling gasholders he considered was the proper thing to do; and especially in the case of a growing town. When constructing a single-lift holder, why should they not make it a double one? They obtained a double or treble lift without the cost of an additional tank. All they required was the shell of the lift, and the cost of putting it in. They could easily see the immense gain of having a middle lift, without having to go to the expense of a tank or connections.

Mr. CRIPPS suggested that the question of pressure would have to be considered. If they put a new lift to a gasholder, they added to the weight; and this increased the back pressure. This caused extra expense; and it was worth consideration.

Mr. RIDLEY could not off-hand say that any additional expense was caused; for the simple reason that he kept a weekly record of the cost of manufacture, and he found that he could produce gas as cheap, or even cheaper, with extra pressure.

Mr. J. HEPWORTH (Carlisle) expressed the indebtedness of the members to Mr. Wright for the paper he had been good enough to read. He was very glad it was suggested to the author that he should tabulate for them the very interesting and valuable information which they saw in the tables now before them. The paper was mainly an argument for telescoping gasholders rather than erecting additional ones. He hoped the day was now past for any such argument to need very much enforcing. It was evident that, if there were no unfavourable circumstances, it must be much better and considerably cheaper to telescope a gasholder, by putting in a second or a third lift, than it would be to go in for a new holder. The only point worth considering was, he thought, how far it might be safe to do this; and some of them, though a long way off from Rotherhithe, had been watching with much interest the experiments in that direction which had been carried out there. So far as the figures in Mr. Wright's paper referred to it, and so far as the information which he possessed otherwise went, the experiments seemed to have been very

satisfactory indeed. Everyone who had to do with the designing of gasholders in these days, should be wise enough to prepare for the telescoping of the holders in the future. The cost of the tank was the same; and the expense of preparing to telescope the holder (say) ten years hence was very little. It therefore appeared to him to be almost folly to construct a gasholder without keeping this matter in view. The last few years he had constructed several gasholders; and in every case he made provision for telescoping, in the interests of those who should come after him, either for the addition of a second or a third lift. Of course, this subject was not new. Everybody knew that it was cheaper to telescope a gasholder than to start *de novo*; but it had been forced upon their attention recently very much more than previously by what had been done at Rotherhithe. With reference to the increase of pressure, there was no doubt that some extra cost was entailed; but this would be found to consist very largely, he should think, in the first outlay for the exhausters and the other plant necessary for overcoming this pressure. The actual working cost would be very little indeed.

Mr. C. SELLERS (York) said he was in the very happy position which had been referred to, of not needing to prepare for any increased storage of gas. They were pretty well provided for a considerable time. He had been much interested in the discussion, and felt that he could not add anything to it. He thought the case was clearly and strongly made out in favour of the proposition of Mr. Wright, to provide increased storage capacity by means of the telescopic principle; and all the arguments, he thought, in favour of it had been so clearly put before them, that he should say there would not be two opinions regarding what had been said for that principle. Especially, he thought, they would all agree with the prudence pointed out first by Mr. Ridley, and then made very clear by Mr. Hepworth, of providing for the future extension of the holder when first building. In doing this, the cost was, of course, a very strong argument; and the fact of Mr. Wright bringing the principle prominently before them that day would fix it in their mind, and he was sure everyone would reap considerable advantage from the paper. It was not a very debatable subject; but they would all be greatly benefited by the paper.

The PRESIDENT remarked that they had with them a prominent member of the Manchester District Institution of Gas Engineers—Mr. Booth, of Southport—who perhaps would like to make a few remarks on the subject before them. He (the President) might just mention that Mr. Gadd, who had recently figured very prominently in this matter, was a resident in Manchester, and probably Mr. Booth might tell them something which had been stated at the Manchester meeting.

Mr. BOOTH said that unfortunately he was prevented from attending the meeting of the Manchester Institution, when Mr. Newbigging described Mr. Gadd's invention and models were exhibited. He regretted very much indeed he was not able to be there, because, beyond what he had seen of the paper, he knew nothing; and he was looking forward with interest to the discussion which was to come on at their next meeting. With regard to the paper read by Mr. Wright, he might say that he heartily agreed with previous speakers. He thought that, as a rule, it was decidedly the best way of increasing gasholder storage. He was surprised to find that morning, on looking round the Stockton Gas-Works, that his friend Mr. Ford had put a third lift to his holder. He was not aware of this before. Mr. Ford, as they knew, was conservative in many things; but he (Mr. Booth) was glad to say that he had stepped out, and had not been afraid to advance in that line. He himself would soon have to increase the capacity of his holders; but whether or not he could adopt the principle advocated by Mr. Wright and other engineers he was not sure. It happened that they could not carry their tanks below the ground, as they met with quicksand when they got about two or three feet down. All their tanks were constructed above ground, so that with the tank alone they were 30 feet above the datum line, and the gasholder was towering up to a very great height. It would, therefore, be a matter for him to consider, in a future extension of gasholder storage at Southport, whether he should put up a third lift to his existing holders. As he had already stated, he concurred with all that Mr. Wright had said, and agreed with previous speakers.

The PRESIDENT, before asking Mr. Wright to reply to the criticisms which had been passed, said he would like to state that in the case of his Company additional storage was a matter which would shortly engage their attention. He had been down to Stockton to see what their friend Mr. Ford had done before commencing anything in their own case. He was rather afraid they were not placed in a similar position at all to Mr. Ford, who had two or three gasholders in addition to a large one. With them their large holder was practically the holder. They had another, a small one, but it would not be of very much service if the large one were thrown out of use for a considerable time. So he was afraid that in their own case the troubling of the gasholder would not be of much benefit to them at present. As Mr. Wright had said, it was not desirable for them to have "all their eggs in one basket;" and he thought that in their particular case they should almost be driven to the necessity of providing another gasholder. But he certainly thought that the advantages to be derived from doubling or even trebling were so great that, in all cases where it could be done—if there were no circumstances to prevent it—they ought to adopt this plan. He saw a short time since that either four or six holders had been trebled at Bradford. There they obtained a considerable increase of storage at a great

saving of cost; and had they not been able to get this increase without additional land being required for tanks, it might have been a very costly matter to obtain parliamentary powers for the acquisition of additional land. For a few years, at all events, this had been staved off by trebling their gasholders. As he had already said, they were all very much indebted to Mr. Wright for the valuable records he had placed before them. He (the President) knew very well that the members would give him their hearty thanks for his paper; and he would ask some one to propose a vote after Mr. Wright had replied.

Mr. WRIGHT said he was sure the remarks which had been made on his paper had been extremely kind; and he had really nothing to reply to. Any criticisms which had been passed had been answered by members who had taken part in the discussion. He could only thank the meeting for the very kind reception they had given him.

Mr. FORD said he had great pleasure in proposing a hearty vote of thanks to Mr. Wright. He had not taken any part in the discussion, because he felt that he could not have done justice to Mr. Wright's paper. If they had had the figures before them, and been able to digest them a little, they might have come forward with something satisfactory; and he should have been delighted to enter upon the subject from his own point of view. There was no doubt that he had successfully trebled a large gasholder, which had worked for three years in a way that was quite satisfactory to him. Unfortunately, it was not in the first instance arranged for trebling; and they had to put in operation the process of cutting and carving to some extent before getting in the third lift. But, with all the trouble and inconvenience attached thereto, they obtained an addition at a very moderate cost, which they would not have done by placing another tank alongside the existing one. Trebling a holder, he knew, was somewhat difficult; and he was glad to hear Mr. Cripps make the statement he did. He could not agree with Mr. Ridley that pressure was of no account. He had always found that pressure was of importance in a gas-works. Without going into the matter so as to lay it before them, as he might do some day, he must say that he had felt it to be a drawback, but nothing to correspond with the advantage to be gained by the trebling of a holder. Therefore he agreed with Mr. Wright's theory, and was at one with Mr. Hepworth in thinking that when holders were first built they should make preparation for trebling them. Since Mr. Wright came amongst them 16 or 17 years ago, he had been a friend to all gas managers, inasmuch as he was able to save them from much heartburning by giving them information which they could not otherwise obtain. He could assure those who did not know Mr. Wright except through his paper, that, if they had any difficulty, they would find him always ready to help them in every way.

Mr. R. BRIDGE (Doncaster), in seconding the proposition, said that he had great pleasure in doing so. They had all listened attentively to Mr. Wright, and would be much benefited by his paper. It was quite clear to him (Mr. Bridge), and it appeared to be so generally, from the way in which the matter had been received by the members, that telescoping was a very cheap form of increasing storage capacity, more especially in crowded localities. In his own case, he had a gasholder of very large diameter, but very shallow. It had been prepared for telescoping; and he had no doubt that the principle advocated by Mr. Wright might be applied to it. He did not know what was to be the future of gasholder construction. He had had the pleasure of seeing Mr. Gadd's models, and they certainly appeared to him to be a very great advance upon the present style of building these structures. If the thing could be carried out as they were assured by Mr. Gadd it could, it would be something like a revolution in gasholder making. However this might be, he was sure they were all much indebted to Mr. Wright for the paper he had brought before them.

The motion was carried unanimously.

Mr. WRIGHT, in acknowledging the vote, said he was always willing to do what he could to contribute to the success of their meetings.

Mr. ASHMORE remarked that he had recently taken out a patent for telescoping—doubling or trebling—gasholders; and he hoped at the next meeting to read a paper on the subject, and perhaps submit a model for erecting holders without framing at all.

M. PERRET'S DUST-FUEL FURNACE.

Mr. C. SELLERS (York) said it occurred to him that he might perhaps make a suggestion with regard to M. Perret's dust furnace. He did not know if anyone there had it in use; but about a month ago they had it fixed to one of their boilers at the York Gas-Works, and it had been of very great advantage. As they knew, he had always been much in favour of breaking coke, in preparing it either for domestic use or for slow-combustion stoves, which were now so common in all large towns; but there had been a drawback to the process, inasmuch as the breaking of coke created a certain amount of exceedingly small breeze, which was almost unsaleable—only fetching from 2s. to 2s. 6d. per ton. They were in the habit of riddling it, and getting perhaps 4s. per ton for a portion of it, to be used in greenhouse fires—a sort of nut coko. Perret's dust furnace would consume any combustible dust of any kind. It was so valuable in their case that, although it had been but a short time in use, from the calculations which he had made he had no hesitation in saying they would get back the whole of their capital in the first year's use. They had taken a tender for two furnaces—one for each of their boilers; but they

had only fixed one, as they intended to get a new boiler next year, when they would fix the second one. The result of the test of the first one was such that, as he had said, it would yield back to them the whole of the capital outlay in the first year—a capital of about £60, fixed complete. This was a suggestion which was worthy of the consideration of every gas manager; and it was on the lines of Mr. Wright's paper, and on lines of economy in gas management. Everything that tended to lessen cost in the conduct of gas-works was a decided advantage to gas companies, and also to gas managers, because the less capital they had to make profit to pay interest upon, the more easily they could do their work. It enabled them also to sell gas at a cheap rate; and the cheaper they sold gas, the safer would be their industry, and the more permanent would be gas investments. He had very great pleasure in submitting this matter for consideration; and he would be pleased to answer any question respecting the furnace.

Mr. J. HEPPORTH (Carlisle) observed that this sounded rather like an advertisement of the invention; but he had no hesitation in saying that whatever benefit might accrue to the inventor, there would also be great benefit to the user. He had employed the furnace himself. It was particularly valuable in his case, because he had three or four outlets for dust and what was worse than dust—the refuse from shale. He found that the furnace used these up most admirably.

Mr. SELLERS laughingly repudiated having introduced the subject for the purpose of advertising the furnace, or for the sake of getting a commission. (Laughter.) He did it solely for the benefit of his colleagues.

The PRESIDENT said he did not for one moment suppose that the view which had just been mentioned was taken of the question. He rather took it that it was a response to what he said in his address, when he asked members, if they did not read a paper, to bring before the Association such matters as had been referred to, so that gas managers, who were so much isolated from each other as not to be able to see every day the improvements that were taking place, might have an opportunity of knowing from those who had used new processes how they worked. A step in the right direction had been taken. He had not himself tried this furnace, though the patentee had been down to see him with reference to it. In his own case, all the breeze they made they used themselves, in preference to coke or coal, for their steam-boilers. In addition to this, they had a great demand for it in the town, though at present they were not able to sell any. They found it answer their purpose very well. At present they were using coke for their boilers because they had not sufficient breeze. For their exhaustor boiler, they found breeze to answer equally well, with a saving of 4s. or 5s. per ton. In places, however, where there was no demand for breeze, this furnace was a step in the right direction; and it would also tend to reduce the price of gas. He believed in introducing anything which would yield 10 per cent. on the outlay. If anyone could prove to him that an invention would realize 10 per cent. return upon the original cost, he was always ready to introduce it, or to consider its introduction, provided he saw no disadvantage in its use. In this case he thought the invention was one which might be used with considerable advantage.

VOTES OF THANKS.

Mr. R. BRIDGE (Doncaster) thought it was their duty to record their thanks to the President for his very able address that day, in which he had brought matter before them for their entertainment and for their future profit. He followed the address through with a great deal of pleasure; and he was sure that the seeds of knowledge which the President had sown would bear fruit, and that, too, in the not very distant future.

Mr. G. A. ALLAN (Willington) seconded the motion. In doing so, he advocated something being done with reference to the formation of a Committee to try and effect an undertaking about the sizes of gas-retorts. There was, he said, a great deal more in this matter than many gas managers seemed to think. If a maker had to produce some 40 or 50 different sizes and patterns of retorts in the course of a year, he could not keep a stock. Supposing a manager had one or two retorts broken when on the road to the works, and the maker had not any left, a bed was at once laid idle. Instead of merely making a suggestion, he thought something ought to be done. The President should name a Committee, so that they might consider the subject, and report at the meeting in May. There was, again, the subject of the consumption of gas in gas-engines. Gas managers often recommended gas stoves and engines to the public; but they did not use gas-engines themselves. If they required more power, they put in a boiler and steam-engine. Why did they not employ a gas-engine instead? They would find it a great deal cleaner and cheaper; and they could then urge it with more freedom upon people outside. He had great pleasure in seconding the motion, because a better or a plainer address to gas managers he had seldom heard.

The resolution having been agreed to,

The PRESIDENT expressed his great obligation to the meeting for their kindness to him. If, he said, they had asked him to design any part of a gas-works, he should have gone to work with a very much lighter heart than he did to write a presidential address. It was something altogether new to him; and if anything he had said that day had tended to interest them, he was amply repaid for the trouble he had taken in the matter by the vote of thanks which they had just accorded to him. He might say that, so far as the North of England Association was concerned,

and all other Associations, he should be glad to contribute what he could to the industry by which they earned their bread. What Mr. Allan had said about the employment of gas-engines embodied a view of the circumstances which ought to be taken more into consideration. As they would see, when they went round his works, he had a small gas-engine which blew the bellows in the blacksmiths' shop, and another gas-engine which worked a lathe and other machines in the fitters' shop. They had not gas power in the other parts of the works, for the simple reason that they were not prepared to throw out plant which was otherwise good in order to introduce gas; but when opportunity occurred, they should be glad to make use of gas.

Mr. HEPPORTH, on behalf of the Association, proposed a resolution acknowledging the kind reception which had been accorded to the members by the Hartlepool Gas and Water Company.

Mr. J. NICHOLS (Darlington) seconded the motion, which was unanimously adopted.

The PRESIDENT remarked that, as soon as he mentioned to the Directors of the Company that the Association intended to meet there, they responded with a desire to make the gathering as agreeable as possible.

Mr. FISHER thanked the meeting very warmly for their kind vote of thanks. The Directors, he observed, were extremely anxious that the visitors should have a pleasant day; and he himself hoped that, notwithstanding a little damp outside, some of them would enjoy the view of the works, and also would go out with the steamer and inspect the extensions which had taken place at the Hartlepool breakwater, and in the town.

This concluded the business portion of the meeting.

The company afterwards went round the gas-works, escorted by Mr. Bower. In the course of the inspection, one heard constant expressions of satisfaction at the substantial and well-appointed appearance of the works, and the perfect condition in which everything is kept by Mr. Bower. Most interest appeared to be taken in a small plant for working the Claus process, which had, however, been in operation, for too short a period to allow of results being stated. A very complete sulphate plant also claimed attention, as did also a retort-setting which Mr. Bower is at present putting in, in which the air passages are arranged with a view to giving some of the advantages of regeneration without going below the usual foundations; it being impossible, on account of water, to go down beyond 2 or 3 feet. The party afterwards visited the pumping station in connection with the water supply of the town. An engine pumping 150,000 gallons of water per hour, partly to cisterns adjoining the station, and partly to a reservoir four miles away, was seen at work. On leaving the water station, the Company drove through the extensive timber yards which are quite a feature of Hartlepool, to the docks at East Hartlepool, where they embarked, and were taken to see the extensive breakwater and seawall improvements of recent years. The short trip was very enjoyable. Landing at West Hartlepool Docks, the members and their friends repaired to the Royal Hotel, where, at four o'clock, they sat down to dinner, under the presidency of Mr. Bower.

A NON-EXPLOSIVE FOR BALLOONS WANTED.—The Council of the Balloon Society have received from Captain Campbell an offer of a prize of 100 guineas to the inventor of a non-explosive gas suitable for ballooning purposes. The Council have sent a copy of the letter to the various gas managers, inviting them to compete.

THE DINSMORE GAS PROCESS.—At the meeting of the Widnes Local Board on Tuesday last, the Gas Engineer (Mr. Isaac Carr), in the course of his report, referred to the Dinsmore process of coal carbonization, and said it had been in continuous operation at the gas-works since the end of July last, during which period upwards of 4 million cubic feet of gas had been produced. They were at present making from Aldwarke Main coal, without any canal, 13,000 cubic feet of gas per ton, varying in quality from 20 to 24 candles.

ELECTRIC LIGHTING IN MADRID.—The Madrid Correspondent of *Industries* says that the electric light installation in the Opera House is the most important in Spain. There are three boilers of 80-horse power, and four engines, each of 60-horse power, which are coupled direct to the dynamos. The interior of the building will be entirely lighted by Swan incandescent lamps. Of these there are altogether 2800; but it is not expected that more than 2400 will be used at one time. There will be five or six arc lamps placed outside the building.

THE METROPOLITAN BOARD AND GAS TESTING.—At the meeting of the Metropolitan Board last Friday, the references to the Works and General Purposes Committee of March 27, 1885, and April 22, 1887, on the subject of the legalization of gas-tests carried out with portable photometers, and of Aug. 5, 1887, on standards of light, were discharged. The Special Purposes Committee reported the resignation of Mr. C. N. Hake of his appointment as Gas Examiner, and recommended that the question of the appointment of a successor be referred to the Committee, with authority to submit the name of a qualified candidate for election by the Board. The Committee also stated that the new gas-testing place of the South Metropolitan Gas Company, at Woolwich, has been completed, and will shortly be ready for use, and recommended that the question of the appointment of an additional Examiner be referred to the Committee, with authority to submit the name of a qualified candidate for election by the Board. The recommendations were approved.

Register of Patents.

INTEGRATING THE FLOW OF LIQUIDS.—Deacon, G. F., of Liverpool. No. 12,627; Sept 17, 1887. [1s. 6d.]

This is a modification of the apparatus employed to record graphically the volume of the flow of water through a pipe or conduit at each and every instant, described in former patents of the same inventor—viz., Nos. 937 and 4264 of 1873, No. 50 of 1875, No. 105 of 1879, and Nos. 7679 and 8464 of 1886. The specification of the present patent is very lengthy; and an abstract of it could not be understood without reference to the nine sheets of drawings by which it is accompanied. The principal claims are: 1. In apparatus for integrating the flow of liquids, in which the physical position of a floater, disc, or other mechanical part in relation to a zero is or may be connected by a mathematical equation with the corresponding volume of flow, the substitution for such mathematical equation of a mechanical arrangement in which a device such as a cam, spiral, or their equivalent is introduced, and by which the corresponding volume is ascertained. 2. In such apparatus the combination of a disc operated by a clock, and an integrating-wheel driven thereby, and driving a counter; the planes of inclination of the integrating-wheel and time-disc being varied by the motion of the water through a water-way of a meter, through the agency of a cam, spiral, or equivalent. 3. The combination of a disc—operated by a water-wheel or its equivalent—and an integrating-wheel driven thereby and driving a counter; the planes of inclination of the integrating-wheel and disc being varied by the rise and fall of a floater by the agency of a cam, spiral, or equivalent. 4. The combination of a disc actuated by a clock, a paddle-wheel, or their equivalent, and an integrating-wheel driven thereby and driving a counter; the planes of the disc and integrating-wheel being varied by the motion or level of the water in such a manner that the counter registers the correct volume passed between any two observations. 5. In apparatus for integrating the flow of liquids in which the equation between the physical position of the meter, disc, floater, or equivalent part of the apparatus actuated by the water, and the volume per unit of time (either by varying the section of the water-way, or by introducing a cam, spiral, or its equivalent) is or may be caused to be the equation to a straight line, the combination of a disc actuated by a clock or by the water, and an integrating-wheel driven thereby; such integrating-wheel having its axis parallel to, and having a motion parallel to a radius of such integrating-disc in such a manner that, moving from the zero position at or near the centre of the disc to any given maximum position on the radius of the disc, the counter actuated thereby receives a motion proportional to the volume of flow.

REGENERATIVE GAS-LAMPS.—Marsh, T. G., of Lytham. No. 15,344; Nov. 10, 1887. [8d.]

This is a modification of an arrangement of lamp for which the present inventor applied for a patent last year (No. 2708), but subsequently abandoned it. In his application for this earlier patent, he made reference to a collar or ledge situated beneath the horizontal perforations in the burner so as to assist in steadying the flame and increase its luminosity. The patentee, however, found that, owing to the heat generated in the burner, the perforations were apt to become choked, and the collar or ledge became coated with carbonaceous or sulphurous deposits from the gas; thus injuring the form of the light. To obviate these defects, and to keep the burner and ledge sufficiently cool to prevent this injurious deposit, the lower part of the burner has now been prolonged, so as to transmit part of the heat in the burner to a point removed from the perforations; thus reducing the temperature at the perforations to a pitch which will not cause deposition. The collar or ledge is also insulated from direct contact with the foot of the burner to protect it from overheating. To effect this, an extension is screwed to the foot of the burner, and a washer or packing of asbestos, steatite, or other heat-resisting and non-conducting material or composition is interposed between the extension and the foot of the burner. The extension is so fashioned as to present the ledge or collar beneath the perforations; but owing to the non-conducting material between the extension and the burner, and owing also to the heat-absorbing prolongation beneath, the burner and collar remain comparatively cool. In a pendant lamp in which the gas supply comes from above, the extension may be prolonged downward toward the bottom of the glass shield; and it may be made conical or cylindrical, hollow or solid, have a fluted or corrugated surface, be provided with radiating fins, or any form best calculated to radiate the heat drawn from the proximity of the burner. In a lamp supported from beneath (upon a bracket or standard), and deriving its supply of gas from below, the prolongation from the burner is arranged in the form of a tube, either with or without perforations. When the tube is perforated, a supply of air enters from beneath, and, escaping in a heated condition through the perforations into the interior of the glass shield, unites with the heated air coming from the regenerative arrangement above, and assists to feed the flame. For convenience of lighting, the glass is carried upon a sliding gallery supported upon a helical spring. When it is wished to light the lamp, the shield is pushed down against the pressure of the spring; and on being released, the shield pushes closely against the upper part of the lamp, and maintains it in that position.

HEATING THE IGNITING TUBES OF GAS MOTOR ENGINES.—Abel, C. D.; communicated from the Gas Motoren Fabrik Deutz, of Deutz, Germany. No. 17,896; Dec. 29, 1887. [8d.]

This invention relates to apparatus for externally heating the tubes by means of which the combustible charges of motor engines are ignited; and it has for its object to effect such heating by the combustion of vapour produced by the volatilization of benzene or other volatile combustible liquid.

For this purpose a closed receptacle (of spherical or other shape) charged with combustible liquid is fitted at top with a tube reaching down inside it to near the bottom, and having an internal screwed thread through which is placed a rod, the lower end of which acts as a valve for closing more or less a small opening at the bottom of the receptacle, through which the combustible liquid can pass in regulated quantities into a pipe conducting it downwards to a point where external

heat is applied for volatilizing the liquid as it flows down. The resulting combustible vapour then passes through a continuation of the pipe to a nozzle or Bunsen burner, where it mixes and enters into combustion with the air. For heating the pipe, any convenient source of heat may be used—such as part of the heat produced by the combustion of the vapour itself, or the heat radiated from the motor engine; but, by preference, the necessary heat is supplied by forming round the small supply-pipe a small annular chamber, having at the top a number of jets, and communicating by a small hole (regulated by a screw-plug) with the interior of the pipe; so that a portion of the vapour generated passes into the annular chamber, and issues through the jets thereof. In order to produce the requisite quantity of vapour for supplying these jets in the first instance, a cup is fixed on the supply-pipe underneath the annular chamber, for the reception of a small quantity of volatile combustible liquid which is ignited. The apparatus may be used in combination with any form of Bunsen or other burner and igniting-tube.

GAS-BURNERS.—Mills, B. J. B.; communicated from C. S. Upton, of New York. No. 10,996; July 30, 1888. [8d.]

The invention has for its object the construction of a gas-burner in which a full supply of air is conveyed evenly both inside and outside of a circular gas-flame. The burner is constructed with an annular gas chamber connected with the gas-pipe, and through which gas passes to the jets. Outside this annular chamber, and between it and the chimney, air is supplied to the outside of the flame; its flow being moderated and directed by screens. The air passing up within the annular chamber is gathered into a perforated thimble, which fits the inner cylindrical wall of the chamber closely. A screen is also provided covering all the space under the burner, so as to moderate the flow of air passing to the burner.

Fig. 1 is a perspective view of the burner; and fig. 2 a vertical sectional view of it. Fig. 3 is an under view; the lowest air-screen being removed and part of the gas-supply pipe broken away. The nozzle of the burner has three or more hollow arms A, which support the upper part of the burner, and supply gas to the annular chamber B with jet apertures at top. C is an air chamber. The chimney of the burner, resting upon the ledge, does not allow any air to be supplied to the flame from the side; and it is thus compelled to pass through the perforations, which are made of different sizes, so as to supply air evenly while interrupting its flow sufficiently to prevent the jets of air from striking the flame with such force as to cause it to flicker. The thimble D, which is preferably slightly converging, fits the inner wall of the chamber B, so as to take up all the air passing between the arms A. A second thimble E, within the first, is made with large perforations, so as to break the force of the air currents before they strike the outer thimble D. The latter is provided with smaller perforations, which supply the air evenly to all parts of the flame, and insure a complete and steady combustion. But to further steady the flow of air both from the inside and outside of the annular chamber, the shell F is provided, spreading from the burner nozzle to the chimney ledge, and containing large and numerous perforations.

GAS-STOVES.—Meidinger, H., of Carlsruhe, Germany. No. 11,157; Aug. 1, 1888. [8d.]

The arrangement of this gas-heating stove is shown in the accompanying engraving, in which fig. 1 is a vertical central section of the

stove (the surrounding casing being omitted); fig. 2 is a horizontal section of the lower part; fig. 3 is a vertical central section of a trifling modification; fig. 4 is a transverse section of the top portion of the stove; and fig. 5 is a horizontal section of this top part.

The stove rests on feet between which the air freely enters the inner space of the heater. By the outer cylindric side B and the inner cylindric side C is formed an annular slot-shaped passage. In order to maintain the two sides at the same distance apart, they are provided with radial ribs—four to eight in number being provided. The inner cylindric side C is connected at its lower extremity with a conical portion F, whereby the annular combustion chamber is formed. Within this chamber is arranged an annular gas-pipe G provided with numerous burners, the intervals between which are so small that the gas streaming forth from all the burners is gradually lit as soon as the jet of gas near the fire-door H is lighted. At its top, the inner cylinder terminates by a cylindrical portion I of smaller diameter, and provided with a flange that connects it to the outer cylindrical side B. In this manner an annular chamber is formed, where the cooled products of combustion collect before escaping through the smoke-pipe K. For the purpose of allowing the gases, which enter the portion of the collecting chamber opposite to the exit-pipe to flow directly to this pipe, a passage or tube M is provided inside the cylinder I. Within the cylinder C, which is open at its upper and lower extremities, are arranged one or more metal plates or sheets (as shown at N), extending from the top of the cylinder to the bottom edge of the conical portion F. On being heated, these plates add to the surface, which imparts caloric to the current of air continually passing through the cylinder.

Fig. 3 shows a modification of the stove, wherein both sides of it are kept apart at an unvariable distance, by means of vertical ribs formed on or suitably attached to either one side or the other, or partly to one side and partly to the other.

EXTENSION OF PUBLIC LIGHTING AT BECKENHAM.—In consequence of the reduction made in the price of gas by the Crystal Palace Gas Company, the Beckenham Local Board have decided to extend the area of their lighting district.

PROPOSED ELECTRIC LIGHTING OF HARROW.—Last Wednesday evening a meeting of the ratepayers of Harrow was held to consider the advisability of adopting electric lighting in the town. Mr. Russell Biggs presided. Mr. Frank Taylor expatiated on the advantages, from his point of view, of the electric light; remarking that this light was bound to come sooner or later, and that the time had arrived when it could be supplied as cheap as, or cheaper than gas. He did not, however, cite Barnet as an instance of the successful introduction of the system of illumination he advocated. Mr. W. F. Taylor gave some figures as to the relative cost of the electric light and gas; stating that the former had the advantage to the extent of 4s. per 1000 hours of lighting per burner. After some discussion, it was resolved to ask the Local Board to investigate the matter.

THE NORTHERN COAL TRADE.—The activity in the coal trade of the North has been further increased by the apprehensions of strikes in Yorkshire. In such an event, it is probable that the Humber coal trade would be seriously interfered with, and that vessels would go to the Tyne and Durham ports instead. The steam coal trade has decidedly stiffened under the belief that this is probable; and a considerable number of orders have been given out; so that the prospect for the winter is better than for several years—that is, as far as the bulk of trade is concerned. In gas coal there is great activity, and most of the collieries yielding this class of coal are now actively at work. For additional orders, the full price has to be paid; and, indeed, one or two of the gas collieries shipping at Sunderland now ask 7s. 3d. per ton for coal. The miners were working rather better last week; but the demand took away the coal rapidly—some users desiring to stock in case of possible suspension of work in some of the coal-fields. Manufacturing coal is steady at the advance; and there is a fuller inquiry for coking coal. Thus, all round, the coal trade seems brisker, and with a full production and a fair demand there is the prospect of a good winter's trade, which labour troubles elsewhere may cause to be even better. As yet there is no advance in prices in the Northumbrian district in consequence of the difficulties; but it is quite probable that such an advance may be declared soon, unless there should be a settlement of the disputes.

Correspondence.

[We are not responsible for the opinions expressed by Correspondents.]

MR. HELPS'S PIPE EXTRACTOR.

SIR,—I have read with some amusement your remarks in the JOURNAL for the 25th ult. (p. 542) on Mr. Helps's patent, seeing that about 33 years ago I made a similar machine for the same purpose. It was tried with 4-inch pipes, but did not save much, if anything.

West Ham Gas-Works, Oct. 11, 1888.

E. H. THORMAN.

MODIFICATIONS OF HARCOURT'S COLOUR TEST.

SIR,—I thank Mr. Leicester Greville for his courteous letter in the last number of the JOURNAL. I am sorry that there should have been a mistake in my letter in the issue for Oct. 2, for by some means 20 c.c. was converted into 70 c.c. of water. As a matter of fact, if gas normal solutions are used, 10 c.c. of solution is sufficient; and if Mr. Greville will try the experiment described in my letter with 20 c.c. instead of 70 c.c., he will find that what I said was quite correct.

Ramsgate, Oct. 12, 1888.

W. G. HICKS.

GAS SUPPLY IN JAPAN.

SIR,—In your last issue there was a paragraph, headed as above, in which it was stated that Mr. Watson Smith, Lecturer in Chemical Technology at the Owens College, Manchester, had heard from his friend Mr. W. Newbigging, Manager of the Tokio Gas Company, that the President of the Company (Mr. Shibusawa) has recently been enabled to announce that a substantial reduction in the price of gas will take place—viz., from 3 to 2.70 yen per 1000 cubic feet, with discount; and he gives Mr. Newbigging a side-winded compliment for his skill and management. I should not have noticed the matter, only a very short time ago another paragraph appeared in the JOURNAL eulogizing the Tokio Gas Manager for his great skill, &c., &c., before he had had time to look about him after arriving in the country. Taking into account that the mines are convenient to, and that the coal is stored in the Tokio Gas-Works at about \$4 per ton, and that they pay their stokers \$10 per month, the gas still runs high in price—10s. 9d. per 1000 cubic feet as reduced. I, however, cannot give any opinion as to Mr. Newbigging's skill and management; but if your information of the latter is derived from as good a source as that from which you learnt that the Japanese yen is equal to about 2s. 9d. of English money, very little credit can be placed on it. There is no Japanese coin equal to about 2s. 9d. of our money; a Japanese yen is equal to 4s. 2d. English—a 5-yen piece being equal to our sovereign.

Dungannon, Oct. 11, 1888.

R. ROSS.

SETTLEMENT OF A LONG-STANDING GAS ACCOUNT.—Mr. C. Sellers, the Engineer and Secretary of the York Gas Company, has received a letter from a distant anonymous individual, enclosing, as the writer states, "five £1 orders for an account I have owed for many years, and interest, and to pay for an answer," in a newspaper.

GAS EXHIBITION IN KENDAL.—An exhibition of gas appliances was opened in the Market Hall, Kendal, last Tuesday night, by Mr. W. H. Wakefield, Chairman of Quarter Sessions. It was arranged by the Kendal Gas and Water Company, and included all kinds of appliances for the consumption of gas for illuminating and domestic purposes.

ROTHERFIELD AND CROWBRIDGE GAS COMPANY, LIMITED.—This Company are issuing a prospectus in which they state that they have secured an eligible site; the Marquis of Abergavenny having granted a lease for the requisite land on which to erect their works at Crowbridge, Sussex. The capital is £6000, in 1200 shares of £5.

THE CAPITAL OF THE FAVERSHAM GAS COMPANY.—The Faversham Gas Company are going to liquidate, in order to pay about 30s. in the pound to the shareholders. The capital of the Company is small; but the plant and business are valuable. As a consequence, there is to be a re-arrangement by which each shareholder will get £150 worth of stock for £100 worth of shares.

PROPOSED ADOPTION OF ELECTRIC LIGHTING AT HENDON.—Encouraged, doubtless, by the success (?) of the electric lighting of Barnet, a member of the Hendon Local Board—Mr. Yule—has notified his intention of moving, at the next meeting of that body, that the Solicitor be instructed to apply to the Town Clerk of Barnet for particulars as to the price paid for electric lighting there, with a view of ascertaining whether a saving of the ratepayers' money might be effected by the adoption of the new light at Hendon.

THE MANSFIELD IMPROVEMENT COMMISSIONERS, AND THE WATER-WORKS.—At the meeting of the Mansfield Improvement Commissioners last Friday, Mr. James gave notice of a motion to refer to arbitration the question of the terms on which the Commissioners could acquire the undertaking of the Mansfield Water Company. He reviewed the past proceedings in the matter, and remarked that, inasmuch as there was only £6000 difference between the amount already offered by the Commissioners and that asked by the Company, the matter should be settled in the manner suggested.

REDUCTIONS IN PRICE.—The Brentford Gas Company have given notice of their intention to reduce the price of gas to private consumers from 3s. 2d. to 3s., and for public lighting from 2s. 10d. to 2s. 8d. per 1000 cubic feet, from the close of the quarter ending at Christmas next. This will mean a saving of upwards of £260 per annum to the Board.—As reported in another column, the Carlisle Town Council have decided on reducing the price of gas from 2s. 6d. to 2s. 3d. per 1000 cubic feet as from the end of the year.—The Whitworth Vale Gas Company have reduced the price of gas 2d. per 1000 feet as from the 1st inst. The price will now be 3s. 9d. per 1000 feet.

IMPROVED LIGHTING IN ST. JAMES'S.—At the meeting of the Vestry of St. James's, Westminster, last Thursday, the Lighting Committee recommended that it should be referred to them to take into consideration the advisability of fixing street lanterns of improved construction throughout the parish where necessary, with a view to the full benefit being derived from the recent increase in the size of the burners. This was agreed to. One of the members said he had just returned from a tour in the smaller towns of Germany, and he did not hesitate to say that in any second-class city in Germany the lighting was superior to anything found in the Metropolis. London, as a city, was very badly lighted; and St. James's, Westminster, was the worst lighted portion of it.

Miscellaneous News.

METROPOLIS GAS SUPPLY.

The Chief Gas Examiner for the Metropolis (Dr. Williamson, F.R.S.) has presented his report on the quality of the gas supplied by The Gaslight and Coke, the Commercial, and the South Metropolitan Companies, during the quarter ending Sept. 30. The following is an abstract:—

I. With respect to Illuminating Power.—The average illuminating power, in standard sperm candles, at each of the testing stations, was as follows:—

The Gaslight and Coke Company—	
Jewry Street, E.C.	16.4
Kinghorn Street, E.C.	16.7
Dorset Buildings, E.C.	16.7
Ladbroke Grove, W.	18.0
Devon's Road, E.	16.6
Carlyle Square, Chelsea	16.6
Camden Street, N.W.	16.3
Graham Road, E.	16.5
Kingsland Road, E.	16.9
Spring Gardens, Charing Cross, S.W.	16.3
Grove Gardens, Regent's Park, N.W.	16.6
Lambeth Road, S.E.	16.4
Hornsey Road, N.	16.2
Millbank Street, S.W. (cannel gas)	20.8
Commercial Gas Company—	
Wellclose Square, E.	16.5
Parnell Road, E.	16.6
South Metropolitan Gas Company—	
Hill Street, S.E.	16.5
Foster Place, S.W.	16.3
Stoney Lane	16.4
Lewisham Road, S.E.	16.4
Blackfriars Road	16.2

It will be seen from these results that the average illuminating power at all the testing stations was higher than the parliamentary standard. At the Millbank Street and Lambeth Road stations of The Gaslight and Coke Company, the minimum illuminating power was equal to the requirements; and, with the exception of certain deficiencies in the lighting power at the Jewry Street, Camden Street, Spring Gardens, Hornsey Road, Wellclose Square, and Parnell Road testing stations, the minimum was either equal to or above the requirements of the Acts of Parliament at all the testing stations.

II. As regards Purity.—Sulphuretted hydrogen was not present in the gas at any of the testing stations. The average amount of sulphur present in the gas has been considerably less than the quantity permitted at all the testing stations. With the exception of the Jewry Street station (where on four occasions during the quarter slight excesses were reported), the maximum amount present in the gas has been well within the limit at each station. Excepting the City of London testing stations, ammonia was generally present in the gas more or less frequently during the quarter, but only in slight quantities, at all the stations.

THE CHARGES IN CONNECTION WITH THE HALIFAX GAS COAL CONTRACTS.

The following correspondence, bearing upon the impending proceedings arising out of the charges of fraud in connection with the Halifax gas coal contracts, has been forwarded to us for publication. On the 11th inst., Messrs. Cobbett, Wheeler, and Cobbett (Mr. Emor G. Wrigley's Solicitors) wrote to the Town Clerk of Halifax, Mr. Keighley Walton, in reply to a letter addressed by him to Mr. Wrigley on the 4th inst., as follows:—"Having regard to the character and means of Mr. Fox, we have advised our client not to take legal proceedings against him, but to treat his allegations with contempt. We are instructed to state on Mr. Wrigley's behalf that he denies that he has fraudulently substituted another and inferior coal to that which he contracted to supply to the Halifax Gas-Works, or that he has been guilty of malpractices in connection with the Halifax Gas-Works; and he is willing, and hereby offers through us, to render any assistance in his power or give any desired information to the Corporation for the purpose of proving that such charges are false." A copy of this letter was forwarded by the Town Clerk to Messrs. Godfrey Rhodes and Evans (Mr. Fox's Solicitors), who on the next day replied as follows:—"We are obliged by the copy of letter received by you from Messrs. Cobbett, Wheeler, and Cobbett, written on behalf of Mr. Wrigley, and hasten to reply to the base insult and insinuation therein contained, reflecting upon Mr. Fox. If either Mr. Wrigley or Messrs. Cobbett, Wheeler, and Cobbett have any charges to make against our client's character, and will put them into writing, our client will be prepared to meet his accusers face to face in the witness-box, and will not be as long in issuing his writ as Mr. Wrigley has been. Mr. Wrigley and his advisers no doubt would be very glad to escape the exposure consequent on his going into a Court of Law; but in order that the excuse as to our client's means put forward by them may be discarded, we may say that our client will be prepared, within 24 hours after being served with any writ by Mr. Wrigley, to deposit with the Mayor the sum of £1000, provided Mr. Wrigley will deposit a similar amount, and to be held by the Mayor to provide for the result of Mr. Wrigley's action. Our client cannot boast of any large possessions; but if he had adopted the same means of making money which, from information in our possession, Mr. Wrigley appears to have followed, he would no doubt have been worth considerably more. We shall be glad if you will kindly ask Messrs. Cobbett, Wheeler, and Cobbett to state what charges they have to make against our client's character. We may say, in reference to the offer on behalf of Mr. Wrigley to render any assistance in his power, or to give information to the Corporation, that, so far as our client is concerned, and we venture to think so far as the general body of ratepayers of Halifax are concerned, no information he may give will be satisfactory, unless given upon oath, and unless he subjects himself to cross-examination in the witness-box." The draft indemnity to be given to Mr. Alderman Riley by the Corporation will, it is expected, shortly be submitted to the Mayor and Town Clerk for approval.

LEEDS CORPORATION GAS SUPPLY.

ALLEGATIONS BY MR. ELLIS LEVER AS TO THE COAL CONTRACTS.

At the Meeting of the Leeds Town Council last Thursday—the Mayor (Mr. Alderman Searr) in the chair—a discussion took place on the subject of certain communications which had been received by his Worship from Mr. Ellis Lever in reference to the Corporation coal contracts.

Mr. GILSTON, Chairman of the Gas Committee, in moving the approval of the minutes of the Committee, called attention to the following statement contained therein:—"The Mayor attended (on Aug. 1) and read to the Committee telegrams and letters received by him from Mr. Ellis Lever upon the subject of coal contracts. Resolved—That, having heard the Mayor's explanation of his reason for desiring the subject to be considered by the Committee, they are of opinion that there is no sufficient reason

for withdrawing the resolution accepting the coal tenders from the minutes to be approved by the Council to-day." He said that the Mayor received from Mr. Ellis Lever letters intimating that amongst the people tendering for coals were men who were not particularly truthful and honest in their dealings, and wishing to caution the Committee against entering into any contract with people of this kind. Inasmuch as Mr. Lever did not indicate the persons to whom he referred, and the Committee did not know them, they declined to withhold the tenders they were prepared to recommend to the Council for acceptance. They did this, however—they appointed the Mayor, the Town Clerk (Sir G. Morrison), and himself to meet Mr. Lever, and hear what he had to say in the matter; agreeing that if anything substantial to the disadvantage of the men referred to were laid before them, they would not fail to take notice of it. Mr. Lever had not found it convenient to make arrangements to meet them; and he (Mr. Gilston) apprehended that he had nothing to say against any person with whom contracts had been entered into. The Gas Committee, however, were not disposed to leave the matter where it was. They were determined that, sooner or later, Mr. Lever should be asked to meet a deputation of the Committee, in order that he might justify the charges made against one or more of the people referred to.

Mr. DYSON seconded the motion.

Alderman GAUNT reminded the Council that Mr. Lever had already been engaged in one action in regard to coal contracts, and had substantiated every word he had used; and he expressed a hope that the Committee would not, from any punctiliousness, refrain from receiving information from Mr. Lever or any one else. The Council were aware that in Leeds, only a year or two ago, they had coals of an inferior kind sent to New Wortley; and, in fact, that a lot of things were then going on that were very irregular—not that it was the fault of the Gas Committee, because the members could not be present to look after such things. He was quite sure that, if there was anything wrong, the Committee would do their best to get to the bottom of it.

The MAYOR said Mr. Lever had not refused to come and see them; he had engagements which prevented him coming now. However, he was under a promise to come when it was convenient; and therefore he (the Mayor) thought they had better not discuss the matter further at present. When Mr. Lever came, Mr. Gilston, Sir G. Morrison, and himself would hear what he had to say, and would communicate it to the Council or to the Gas Committee.

Mr. HENRY hoped the Council would not be uneasy in reference to this matter. Mr. Lever had not made any allegations against those with whom they had entered into coal contracts. He was aware that discounts had been deducted from accounts in cases where an inferior quality of coal had been sent in.

Sir E. GAUNT: That is a very improper thing.

Mr. HENRY replied that it might not be a proper thing; but if it were found that an inferior article was sent in, it was surely fair that a deduction should be made, and the contractor warned that if he sent any more coal of an inferior quality his contract would be broken. The Gas Committee were quite alive to the matter. There was very little irregularity; in fact, he believed there was none at all. The Council might rest assured that the Committee would not hesitate to probe to the bottom anything they found to be wrong.

Alderman TATHAM hoped the Gas Committee would feel their hands strengthened by the Council in thoroughly investigating these matters, because he believed the hateful practices alluded to were almost universal; and if they could be stamped out, it would be a good thing.

Alderman EMSLEY said the coal contracts of the borough amounted to £150,000 a year. It appeared to him that the Gas Committee had declined to go into the matter as the Mayor requested.

The Mayor interposed, saying he did not request the Committee to withhold the contracts from confirmation. There had been no definite charges made against any person; and the Committee thought it right to go on with the business—intimating that they would like to hear Mr. Lever after the contracts were confirmed. He might add that he did not think the Council need be alarmed in the matter.

Alderman BAKER said Mr. Lever had been urged to attend before the Committee to give any information he possessed, and the Chairman of the Committee had done all he possibly could in the matter; but Mr. Lever had sent a telegram to say it was not convenient to come. When coal of an inferior quality was persistently sent in, the contract was stopped; but when it was only one or two loads that were poor, deductions from the payments were made. The people employed at the gas-works were very cautious; and he hoped they would continue to be so.

Mr. ARNOLD LUPTON pointed out that there might be variations in the quality of coal without any intentional dishonesty.

Mr. GILSTON, in reply, hoped the Council would not suppose that either the Gas Committee or himself would attempt to stop Mr. Lever from carrying out the purifying process he had had in hand for some time. Every gas concern in the country was indebted to him for the exposures which he had made; but, while grateful to him, they must not forget the character of their own people. The Council need not be disturbed about the coal, as every Manager was responsible; and it was his interest to see that he was getting what he paid for. Besides, the coal was tested by an independent analyst once a month. If Mr. Lever could point out one man who had acted dishonestly, there was no member of the Gas Committee who would not be ready to investigate any charge he might bring against any contractor.

The motion was then put and carried.

THE SHEFFIELD CORPORATION AND THE GAS COMPANY.

THE DUTIES OF THE NOMINEE GAS DIRECTORS.—THE ISSUE OF NEW STOCK.

At the Meeting of the Sheffield Town Council on Wednesday last, the members were asked to elect three nominee Directors, to represent the Corporation on the Board of the Gas Company. Before proceeding with the business, Alderman Foster requested some information as to the duties of the Directors. Were they useful or purely ornamental? Mr. Booker replied that they were certainly not useful. The Mayor (Mr. Alderman Clegg) suggested that the votes should be counted before the question put by Mr. Alderman Foster was answered. The votes were then taken; the result being that Mr. Alderman Gainsford, Mr. Langley, and Mr. Franklin were re-elected. Alderman Gainsford, in answer to the question, said it was for the Council to judge of the utility or otherwise of the Directors. Alderman R. T. Eadon thought the Directors were useful, and mentioned instances when, but for their presence on the Board, there might have been ill-feeling between the Corporation and the Company. Mr. Franklin said the nominee Directors were placed on the Board by Act of Parliament. He did not think they were of any great use to the Council—in fact, the Law Clerk of the Gas Company (Mr. W. Wake), when asked what their particular functions were, replied that it was to make themselves disagreeable. He could not say that they had succeeded in fulfilling the idea of the Law Clerk. He believed they had been as successful as their limited powers would permit them to be in attending to the interests of the town. Alluding to the issue of a new class of shares by the Company, he said it

was a question which very seriously affected the town, and one which the nominee Directors took into their careful consideration; and he both spoke and voted against such issue. The Company had uncalled capital of something like £8000, they had large borrowing powers which they had not exercised, and they had uncalled capital on the "E" shares; but notwithstanding this, they had decided to issue new shares. He communicated with the Town Clerk (Mr. Pye-Smith), and ascertained his opinion; and he had also found from the Acts of Parliament that, although the Company had the borrowing powers, they would not be justified in exercising them. The Town Clerk said the question of issuing shares was one for the proprietors to decide, and that no outside authorities had any power to interfere with them. This was the state of the law; and, in his opinion, the interests of the town had not been so well looked after in the past as they might have been. He thought it due to the Council to give this explanation. Alderman Gainsford said he had mentioned the matter of raising new capital to the Law Clerk of the Company; and he clearly pointed out that Parliament had given them the power to issue new shares to the existing holders at their nominal value instead of at their market value. The Law Clerk explained that, at the time the Act of Parliament was passed, it was agreed that the Company should be limited to a 10 per cent. dividend on the one side, but on the other side that they should have the power of issuing new shares at the nominal value of £100 instead of the market value, which, he supposed, would now be about £250. The Law Clerk said that if they had not had the privilege of issuing new shares at their nominal value, they would have been allowed, as other gas companies were, to have gone beyond the 10 per cent. dividend. He pointed out that if the Company had wanted £50,000, they could have obtained it by issuing capital bearing a dividend of £4000 or £5000, instead of £12,000 as by their present plan. The Company, in what they had done, had acted entirely within the scope of their Acts. He mentioned this in order that the Council might understand both sides of the question. Mr. Langley said he was the only nominee Director at the meeting held on the 1st inst. (see *ante*, p. 639), and not one shareholder rose to ask what the money was wanted for. He bore testimony to the efficiency of the Company's works. A formal resolution was then passed re-electing the gentlemen above-named.

ARBROATH CORPORATION GAS SUPPLY.

THE PROPOSED EXTENSION OF THE GAS-WORKS.

A Meeting of the Committee of Management of the Arbroath Gas Corporation was held on Monday last week—Provost ANDERSON presiding—for the purpose of considering the remit from the Commission in reference to the carrying out of the proposed extension and improvement of the gas-works at a cost of about £8000.

Provost ANDERSON explained the object of the meeting, and detailed the steps which had led up to its being held. He afterwards remarked that the position at which the Commissioners had now arrived was either that the extension scheme contained in the remit ought to be carried out, or that the erection of new works should be faced. He had no objection to recede from the position he had taken up, provided those who favoured the new works could show how it could be financially accomplished; but he maintained that the time had now arrived when the Committee should either do the one thing or the other.

Mr. DICKSON said his idea was that the Engineer's (Mr. R. S. Carlow's) estimate for removing the old plant to a new site, and adding whatever additional plant was required, should be practically tested by asking local tradesmen to send in offers for performing the necessary work, and that a Committee of three should be appointed to look out for a site. His firm belief was that a new site could be procured without a penny of cost to the ratepayers. He admitted that Mr. Carlow's estimate might fall a little short; but the transference could, in his opinion, be effected for about £17,000, and as much would be saved annually as would meet the interest on a loan of this amount. He moved a resolution accordingly.

Mr. CARLOW, in reply to a question, said he had withdrawn his estimate for removing the works to a new site at a cost of £15,000, so far as the cost of the removal of the holder was concerned. There might be some difficulty in fitting up the old iron sheets, and also in excavating the whole of the stones of the holder; and he had therefore increased his estimate, so far as it concerned the removing of the holder, by £2000.

Mr. DICKSON said he had never understood until now that Mr. Carlow had withdrawn his estimate of £15,000.

Provost ANDERSON said it had been mentioned at least half-a-dozen times at the last meeting.

Mr. CARGILL remarked that Mr. Dickson's proposals were not so simple as they appeared. At the same time he did not disapprove of the suggestion that an inquiry should take place as to the cost of erecting new works.

Provost ANDERSON said his objection to Mr. Dickson's proposed inquiry was that they could place no kind of reliance upon estimates given by tradesmen who were not assured that the works for which they were estimating were going on. Besides, local tradesmen knew nothing about gas-works. If they wished for a reliable estimate, they must procure it from a gas engineer. If they would go the length of remitting it to such a man as Mr. William Foulis, Engineer and Manager to the Glasgow Gas Corporation, he should have no objection to such a course.

Mr. SANDEMAN held that no new arguments in favour of the extension had been advanced. He considered, therefore, that the Commissioners should consult their constituents at the November elections before doing anything further.

Provost ANDERSON said that he could not understand the position taken up by Mr. Sandeman, after he had consented to the Commissioners engaging Mr. Mitchell to report on the works.

Mr. SANDEMAN replied that he was entitled to change his opinion when he thought he was wrong. He maintained that the Arbroath Gas-Works were as good as any of their size in Scotland, and that the Commissioners therefore were not justified in spending £800 upon them.

Mr. CARLOW remarked that Mr. Sandeman had apparently forgotten that the small gasholder was completely done for.

Mr. DICKSON said he should support Mr. Sandeman's proposition, as a protest against the present site of the works.

After some further remarks,

Mr. CARGILL moved that the following should become the finding of the Committee:—"It was resolved that, before proceeding to carry out the remit made to them, the Committee recommend that a Special Committee, consisting of Provost Anderson and Messrs. Dickson and Cargill, should be appointed to look out for a suitable site for new works or alternative sites; and the Committee further recommend that the question of the proposed extension of the present works and new works should be remitted to Mr. William Foulis, Engineer, Glasgow Corporation Gas-Works, to consider and report."

A vote was then taken between the motion of Mr. Sandeman and Mr. Cargill's amendment, when the latter was carried by 15 votes to 2; Mr. Michie entering his dissent.

The Committee then resolved itself into a meeting of the whole Board, when the finding of the Committee was unanimously adopted.

STAFFORD CORPORATION GAS SUPPLY.

THE PROGRESS OF THE WORKS.

In the JOURNAL last week we briefly alluded to the visit recently paid by the members of the Stafford Corporation to the gas-works, by invitation of Mr. Alderman Dudley, the Chairman of the Gas Committee. On that occasion, this gentleman gave a short account of the improvements which have been effected in the gas-works during the past few years. In the course of his remarks he said: The first important alteration and extension made at these works since 1883 was the erection of two new lime purifiers and a new shed for slacking and storing lime; also a shed for spent lime. The gas is now passed through four oxide purifiers, each filled with hydrated ferric oxide. In these the whole of the sulphuretted hydrogen is eliminated from the gas; also a portion of the sulphur compounds. The gas is then passed through the new lime purifiers, which take out the carbonic acid, and further reduce the sulphur compounds—the chief benefit obtained by eliminating the carbonic acid being an increase in the illuminating power of the gas. The cost of altering the purifying arrangements was £1500; and we now have a very efficient system of gas purification. Further, the manual labour of emptying and charging the oxide purifiers is reduced to a minimum by means of an oxide conveyer. The next alteration worthy of note is the construction of new retort furnaces in No. 2 retort-bench. No. 1 retort-bench has been rebuilt; the length of the retorts increased from 18½ to 20 feet; and the retorts in this bench are heated by the Manager's (Mr. J. F. Bell's) own system of regenerative furnaces, which, I understand, is being protected in England and America. By means of this system, we can make upwards of 8000 cubic feet of gas per mouthpiece in 24 hours, against 5000 cubic feet in the ordinary settings. The importance of this will be at once perceived when I inform you that, unless a larger make of gas per retort had been made possible, the retort-house would have had to be speedily enlarged. The cost of this extension would amount to £5000, and is thus able to be deferred for some time longer. The cost of rebuilding No. 1 retort-bench and introducing the regenerative furnaces was about £500. Further, the coke used for carbonizing the coal is considerably lowered by means of the improved furnaces. A glance at the printed statement of the gas accounts at once shows this; for I find that during 1883, 2462 tons of coke were sold, and during 1888, 3513 tons, or an increase of nearly 50 per cent. Allowing for the difference in the quantity of coal carbonized—in 1883, 7648 tons, and in 1888, 8637 tons, the increase of coal used being 13 per cent.—and deducting this amount, gives a net increase of over 35 per cent. due to improved retort furnaces. The anxiety caused to the members of the Gas Committee when the serious depreciation took place in the value of residual products—tar and ammoniacal liquor—will be fresh in the minds of the members of this Council. To minimize the loss on residuals, the Committee decided to work up the gas liquor into sulphate of ammonia. I have repeatedly brought before you the advantage gained by the erection of sulphate works, and will now only add that the entire cost of them—viz., £1000—has been recouped by the additional profit made on the manufacture of sulphate. Our sulphate works have been inspected by a number of gentlemen from different parts of the country; and I can claim that they are among the most complete for their size. The obnoxious gases resulting from the manufacture of sulphate of ammonia from ordinary gas liquor are entirely decomposed; and we have here a sample of the sulphur recovered by means of the Claus sulphur-recovery process. Among the minor improvements have been the alteration of the hydraulic mains, and the introduction of new wrought-iron ascension-pipes, on two beds of retorts, so as to reduce the number of stopped pipes; also a new tar extractor has lately been fixed, which completely eliminates all the fine tarry particles from the gas before it is further treated for other impurities. So complete is this elimination, that if a jet of gas be allowed to impinge on white note-paper for 24 hours it will not stain it. For some time the Committee considered the advisability of altering the gas offices, which formerly were very inconvenient to our customers. The alterations speak for themselves; and no doubt will be appreciated by those employed therein and the general public. The total amount of money spent in alterations and extensions during the last five years has been upwards of £5000, the whole of which has been charged to the revenue account. The price of gas has been reduced 6d. per 1000 cubic feet, the meter-rents have been reduced, and the total amount of profit handed over in reduction of the rates during the last five years has been £7900 against £5700 applied in this way during the five previous years.

CARLISLE CORPORATION GAS AND WATER SUPPLY.

THE WORKING IN THE YEAR ENDING JUNE 30.

At the Meeting of the Carlisle Town Council last Tuesday, the Gas, Water, and Baths Committee presented a report on the working of these departments during the year ending June 30 last, accompanied by the usual financial statement. In both the Gas and Water Departments the profits were larger than the Committee anticipated. The amounts payable to the city and district funds were as follows:—City fund (gas profits), £8066 15s. 6d.; district fund (water profits), £4291 5s. 6d.—total £12,358 1s. Deducting the amount previously paid on account, £2000, there was left a balance of £10,358 1s. Having taken into consideration the probable results of the current year's working, the Committee recommended that, from Dec. 31 next, the price of gas should be reduced from 2s. 6d. to 2s. 3d. per 1000 cubic feet within the area of supply, and that the discount on the water charges should be increased from 2s. 6d. to 3s. 4d. in the pound.

Accompanying the Committee's report was one by the Gas and Water Engineer (Mr. J. Hepworth, Assoc. M. Inst. C.E.). In the course thereof he stated that there had been an increased consumption of gas, compared with the preceding year, as shown by the following statement:—

	Coal Carbonized.	Gas Made.	Gas Accounted for.	Gas Unaccounted for.	Per Cent.
	Tons.	Cubic Feet.	Cubic Feet.	Cubic Feet.	
1887	17,343	183,242,000	174,119,000	9,123,000	4.98
1888	17,308	186,916,000	179,371,750	7,544,250	4.03
—35	..	+3,674,000	..	+5,252,750	.. -1,578,750 = -0.95

It will be seen from the foregoing figures that in the past financial year, with a less quantity of coal carbonized by 35 tons, there was an additional production of 3,674,000 cubic feet of gas, an increase of 5,252,750 cubic feet accounted for, and a decrease of 1,578,750 cubic feet unaccounted for. The quantity of gas sold per ton of coal was 10,238 cubic feet; the illuminating power being equal to 19.26 sperm candles. On the subject of the reduction in price, Mr. Hepworth said that, with the figure kept at 2s. 6d., there would be, he estimated, a profit of £8500 in June, 1889, which would be subject to charges for interest, &c., to the extent of £2300; leaving a net surplus of £6200. A reduction of 3d. per 1000 cubic feet would entail a loss of revenue to the extent of £2175, which would leave a net surplus of £4025. The net profits of the Gas Department for the past year were equal to a rate of 9½d. in the pound. With regard to the Water Department, Mr. Hepworth reported that the works and mains had been kept in good order. The total quantity of water delivered in the year was 343,785,067 gallons; being equal to a daily average of 939,311 gallons, or 23.48 gallons

per head of the population. Of this quantity it is estimated that 17·60 gallons were consumed for domestic, and 5·88 gallons for all other purposes. The total bulk delivered in 1887 was 341,865,329 gallons, or 23·41 gallons per head daily for all purposes. He expressed the opinion that the profits for the current year will, in all probability, be equal to those of the year just closed; and in this event the net surplus profits will be £1790. The discount of 12½ per cent. on water accounts, first conceded in 1885, now amounts to £1000 per annum. The net profits for the twelve months reported upon are equal to a rate of 2½d. in the pound. From the accounts following Mr. Hepworth's report, we find that the sale of gas produced £21,763; the rental of meters, £647; residuals, £3691—the total receipts being £26,587. The expenditure on the manufacture of gas was £15,169 (coal costing £9559); on its distribution, £921; management cost £638—the total expenditure being £18,250. The balance carried to the profit and loss account was therefore £8337. The carbonization of 17,303 tons of coal and cannel produced, in addition to the above-named quantity of gas, 7980 tons of coke, of which 2468 tons were used; 207,696 gallons of tar, of which 101,706 gallons were used; and 185 tons of sulphate of ammonia. The water revenue was £6934; the expenditure, £2546—the balance, £4388, being carried to the profit and loss account.

Mr. FORSTER moved the adoption of the report, and also that the price of gas be reduced on the 1st of January next from 2s. 6d. to 2s. 3d. per 1000 feet. He said he considered the results most gratifying, especially in view of the depreciation in the value of the residual products. The increase in the profits must be attributed to good management. There had been 3½ million cubic feet more gas made with 35 tons less coal.

Mr. CREIGHTON, in seconding the motion, said the result, upon which the citizens of Carlisle might be congratulated, had not been obtained by good luck, but, as Mr. Forster had stated, by good management. The leakage only came to about 4 per cent., which was probably the smallest amount in any town in the kingdom; and the quantity of sulphur in the gas was only 9 grains, whereas they might, under the sanction of the Legislature, have 17 or 18 grains per 100 cubic feet. The receipts for tar had been very much reduced—having been only about £180 last year; but they had turned the tar to good account by using it as fuel. He thought the consumers were entitled to the proposed reduction, which might hereafter be still further increased. At the same time the ratepayers were entitled to some advantage from their magnificent property, and the reduction proposed was, he considered, a fair balance between them and the gas consumers.

Mr. SROX congratulated the Committee upon the improvement which had taken place since last year; dwelling specially upon some of the items in the accounts, to show where the improvements had occurred.

The motion was agreed to; and it was further resolved that the discount on the water charges be increased from 2s. 6d. to 3s. 4d. in the pound from the 31st of December next.

THE PROGRESS OF THE BOLTON CORPORATION GAS AND WATER UNDERTAKINGS.

Last Thursday, the borough of Bolton celebrated the Jubilee of its incorporation. The charter was granted on Oct. 11, 1838; so that Bolton was among the first places to take advantage of the Municipal Corporations Act, passed in the session of 1835-6. The Town Council recognized the occasion by having a special meeting, at which they passed a resolution congratulating the borough on its progress. In connection with this event, a digest of the work of the Corporation during its half-century of existence has been prepared by the Town Clerk; and from this document we extract a few details in regard to the gas and water works undertakings.

So far back as the year 1818, the Great Bolton Gaslight Company offered to light the town with gas or oil at the same figure which it was costing the Trustees to illuminate the straggling streets with oil-lamps. This offer was accepted by the Trustees; the Company agreeing to pay £31 10s. annually, in consideration of the Company breaking up the streets, putting the roads and pavements in good condition and repair again, and also having a light fixed upon a pump in the Market Place equal to four ordinary gaslights. The first Engineer of the works was Mr. Ralph Spooner, then connected with the Preston Gas Company; and under his directions the necessary buildings were erected in Gas Street. The first public lamps in the town were lighted by gas on the 1st of May, 1819; the new illuminant being watched with some apprehension by the inhabitants, who had a fear of the invention. The Company made steady progress; and in 1824 a notable event occurred in its history. In that year Sadler, a well-known aeronaut, ascended from the gas-works in his balloon, and was killed in his descent at Whalley. A successful ascent was, however, made, from the works some two years later, when Miss Spooner, daughter of the Gas Engineer, accompanied the aeronaut Green in his balloon. When the town was incorporated in 1838, the Gas Company was a very successful concern; the quantity of gas made being 3½ million cubic feet, or only 1·18th of the present manufacture; the Manager at this time being Mr. James Green. As the town developed, the works at Gas Street were found insufficient to cope with the demand, and, as a result, new ones were erected at Lum Street, these being completed in 1853. In the following year the Company extended its supply to the Bolton Union; and built spacious offices at a cost of £12,000. It was not until 1871 that the Corporation finally decided to take over the gas undertaking; the terms being as follows:—A perpetual annuity of 10 per cent. on the 3909 old, and 6½ per cent. on the 7466 new shares, free from deduction for income-tax, with a bonus of £2 on each share; the total amount of bonus being £22,750. In 1872 this agreement was confirmed by the Bolton Corporation Act. The sale of gas at the time of the transfer was 304½ million cubic feet; now it is about 596 millions—an increase of practically 96 per cent. In 1872 the gas-rental was £51,725; it is now £80,596. The tons of coal carbonized in 1872 were 31,687, as against 62,438 now. The storage capacity has been increased by the erection of a large holder capable of containing 2½ million cubic feet of gas. The total holding capacity of the six holders on the gas-works is 6½ million feet. The gas department is a most profitable concern for the Corporation, for at the last making up of the accounts an amount equal to a reduction of 7d. in the pound on the rates was handed over, besides providing for all contingencies; the total amount paid in relief of rates since the Corporation came into possession being £125,189. The price of gas, too, was reduced a short time ago from 3s. 4d. to 2s. 6d. per 1000 cubic feet. The present Chairman of the Gas Committee is Mr. Alderman Miles.

In 1847 the Corporation took the water-works into their own hands. The old Company had invested in the undertaking £141,928, and they disposed of it for a yearly rent-charge of £4500. In 1863 steps were taken to increase the supply of water, and works were completed in 1876 which raised the capacity of the reservoirs to 7 million gallons per day. The daily consumption of water when the works were taken over by the Corporation was 800,000 gallons; it is now 5,000,000 gallons. The cost of the new works was £338,199; and the total amount of capital now invested in the water undertaking is £773,479. The revenue last year was £49,676, of which £10,000 was applied in aid of the general rates.

PROPOSED PURCHASE OF THE PARTICK, HILLHEAD, AND MARYHILL GAS-WORKS BY THE GLASGOW CORPORATION.

At the Meeting of the Glasgow Town Council last Thursday—the Lord Provost (Sir J. King) in the chair—a recommendation of the Gas Committee, as to the purchase of the undertaking of the Partick, Hillhead, and Maryhill Gas Company by the Corporation—a matter to which several references have lately been made by our Glasgow Correspondent—was brought forward. At a special meeting held on the 16th of August, the Gas Committee had before them a memorandum setting forth the negotiations which had taken place between the representatives of the Corporation and of the Company; and, after a long discussion, it was unanimously resolved to recommend the Corporation as Gas Trustees to conclude an arrangement with the Company for the acquisition of the undertaking, subject to the following conditions:—

1. The price of the undertaking to be as follows:—(1) The holders of the 5½ per cent. preference stock of the Company, amounting to £30,000, to be paid the amount of their stock and 10 per cent. premium. (2) The holders of the ordinary stock of the Company, amounting to £99,300, to be paid the amount of their stock, less 10 per cent. discount. (3) The Gas Trustees to assume the debenture debt and the other current liabilities of the Company, conform to schedule to be subscribed as relative hereto, and to be entitled to all the Company's assets except as after-mentioned.

2. In the balance of the accounts of the Company for the year ended June 30, 1888, before estimating profits, £3000 to be carried to depreciation, less £500 for vested interests.

3. The balance of net profits for the year ending June 30, 1888, amounting (after setting aside the said sum of £3000 and paying dividends, &c.) to £552 16s. 9d., to belong to the Company.

4. The foregoing arrangement to be conditional on: (1) Confirmation by the Corporation, acting as Gas Trustees, and by the shareholders of the Gas Company. (2) The sanction of Parliament being obtained to an extension of the boundaries of the city, in terms of the report by the Boundaries Commissioners, so far as the districts supplied by the Company are concerned; and also to a Bill to be promoted by the Corporation, acting as Gas Trustees, giving effect to the proposed purchase, and conferring on the Corporation, as Gas Trustees, and the Gas Company the requisite powers for carrying the same into effect, and which Bill the Company engage to support as far as in their power.

5. The foregoing arrangement, when confirmed by the Corporation and by the shareholders of the Company, to be binding on both parties till the 15th day of August, 1889, by which time it is hoped the requisite parliamentary authority shall have been obtained for the extension of the boundaries of the city and for the purchase by the Corporation, as Gas Trustees, of the said gas undertaking. In the event, however, of its being found practicable only to obtain, previous to the said 15th day of August, 1889, an Act for the extension of the boundaries of the city, as aforesaid, the foregoing arrangement for the acquisition of the gas undertaking shall remain operative, and the Corporation, as Gas Trustees, shall be bound in the immediately succeeding session of Parliament to promote a Bill to obtain parliamentary sanction for the purchase; and on such sanction being obtained, the transfer of the gas undertaking shall be carried into effect.

6. In the event of Parliament not having authorized the extension of the boundaries of the city previous to the said 15th day of August, 1889, or if, after having so authorized such extension, Parliament shall not in the succeeding session sanction the transfer of the gas undertaking, then the foregoing arrangement and the purchase therein contemplated shall absolutely terminate, unless with the express consent of both parties.

7. Till the said 15th day of August, 1889, or such postponed date as may be afterwards agreed upon between the parties, the gas undertaking of the Company shall continue to be managed by the Directors of the Company and the officers appointed by or acting under them; all the revenue charges, including the fees of the Directors and the salaries of the several officials and employees of the Company, as these have hitherto been paid, being continued and charged, and the Company being entitled to proceed with the additional gasholder at present under contract, and any other capital expenditure already intimated. Should any further capital expenditure be necessary in consequence of extension of business, it shall be subject to the approval of the Gas Trustees; and on obtaining their approval, such expenditure shall also be charged. The Company shall further charge in their accounts during the said period the sum of £3000 in respect of depreciation of plant for the current year; and they shall also, out of revenue earned during the said period, pay (1) the interest on the debenture debt, (2) the dividend on the preference stock, and (3) a dividend not exceeding 4 per cent. per annum on the ordinary stock of the Company, provided that the surplus revenue of the Company, after meeting the several other charges above specified, be sufficient to meet the said dividend. Any surplus, after making the above payments, to belong to the Gas Trustees, who shall defray the expense of carrying out the arrangements and of winding up the Company.

If the foregoing conditions are approved of by the Directors of the Company and by the Corporation, acting as Gas Trustees, the proposed sale shall be submitted as early as possible to the shareholders of the Company for their approval; and, if so approved, shall be embodied in a formal agreement, which shall (so far as they have power to make it binding) be binding on both parties.

At a special meeting of the Committee held on the 2nd inst., they expressed the opinion "that it was desirable that the Corporation, *qua* Gas Trustees, should be in a position to take over the Partick, Hillhead, and Maryhill Gas-Works, in the event of, and as soon as, the boundaries of the city have been extended; and they accordingly agreed to recommend the Town Council, if they approve of the arrangement embodied in the minute of the 16th of August last, to promote a Bill in the ensuing session of Parliament for powers to carry the same into effect, and to authorize the Law Agent and Engineer to take such preliminary steps as may be necessary in connection therewith."

It was decided not to consider the proposal in open meeting; but at the close of the business, the Council discussed the matter privately. No resolution was passed, as the Committee's report will come before the Council at a meeting to be held next Thursday.

THE LAWRENCE GAS COMPANY OF LANCASHIRE AND CHESHIRE, LIMITED. —A Company under this title was registered last week, with a capital of £150,000, in 30,000 shares of £5 each, with the object of entering into an agreement with the Lawrence Automatic Gas Company to acquire their patent rights.

THE COLNE WATER SCHEME.—Considerable progress has of late been made with the water-works at Laneshawbridge, Colne, where a large reservoir to hold between 90 and 100 million gallons is in course of construction. Already about 40 million gallons have been impounded, and the works are making rapid progress towards completion.

BERLIN MUNICIPAL GAS SUPPLY.

According to the report of the Berlin Chamber of Commerce on the working of the municipal gas undertaking during the past year (an abstract translation of which appears in the current number of the *Journal de l'Eclairage au Gaz*), the consumption of gas in the city, notwithstanding the competition of the electric light, increased, as compared with the preceding year, to the extent of 3,448,000 cubic metres, or 4.43 per cent. The greatest development of consumption was experienced in those localities where building operations were being actively carried on; but at the same time the districts in the central parts of the city showed an advance, arising no doubt from the fact that, in spite of the adoption of electric lighting, gas has still a vast field of operations. The total quantity of gas made was 81,274,000 cubic metres (or about 2868 million cubic feet), of which 10,596,865 cubic metres were consumed for the public lighting, 64,190,127 cubic metres by private persons, 692,151 cubic metres in the works and offices, and 5,794,857 cubic metres were unaccounted for. The consumption of "day" gas (comprising that used in the hours between the extinguishing and re-lighting of the public lamps) rose last year to 16,179,200 cubic metres; being equal to 20 per cent. of the total consumption. In certain parts of the city the quantity of gas burnt does not vary during the entire year; but in summer it only reaches 40 per cent. of the winter consumption. The consumers therefore asked for a reduction of 20 per cent. in the price of gas used during this part of the year, as it was employed for other than lighting purposes. The number of gas-engines supplied from the municipal works rose last year from 448 to 452; the total horse power increasing from 1266 to 1502. The slight addition to the number of engines, yet considerable increase in the motive power, is accounted for by the fact that a great many small engines which were formerly employed to pump water in houses have been thrown out of use, owing to the extension of the mains conveying a supply of water under pressure; while the engines used in the production of the electric light have been generally replaced by others of greater power. In Berlin, as elsewhere, gas has a serious competitor in petroleum. During the past year something like 16,000 gas-burners were dispensed with. Beyond this, there were in operation no less than 333 electric light installations, of which 163 were served from the central station in the city, and 170 from private plant. In the latter cases, the necessary motive power was obtained from steam in 124 establishments, and from gas-engines in the remainder. The electric lighting plant comprises 1554 arc, and 22,363 incandescent lamps; showing, as compared with the preceding year, an increase of 818 of the former, and 9658 of the latter. The number of gas consumers on the books was 46,177; being an increase of 1753 as compared with the year 1886. In the private lighting 724,223 burners, and in the public lighting 15,512 burners were employed; the total of these figures showing an increase of 30,629 burners. The average consumption of gas per burner used for street lighting during the past twelve months was 696.15 cubic metres, or nearly 25,000 cubic feet, as against 692 cubic metres in 1886. The average for the private burners was 89.23 cubic metres, or 3150 cubic feet, as against 88.23 cubic metres (about 35 cubic feet less) in 1886.

With regard to the manufacturing operations, only Silesian coal was employed last year in the production of gas; the quantities being 184,756 tons * of Upper Silesian, and 95,333 tons of Lower Silesian. As compared with 1886, the amount of coal consumed showed an increase of 3.35 per cent.; and the make of gas per ton was better. The cost of the raw material was 6,268,435 frs. (£250,737), or 236,767 frs. (£9471) more than in the previous year. The carbonization of the coal produced 177,240 tons of coke—an increase of 7620 tons. Of the total yield, 44,140 tons were employed for heating the retorts, or 157 kilos. per ton of coal carbonized; and there remained for disposal about 8000 bushels. After commencing favourably, the sale of this residual fell off towards the end of the year; and with regard to the current year, it was anticipated that it would be less easily disposed of, owing to the keen competition existing. It is stated that the London Gas Companies send over large quantities at a low price. The selling price dropped to about 3½d. per bushel last year; and a further fall was expected. The sale of the other residuals was not more favourable; and it was necessary to reduce prices. Of tar, 14,195 tons were produced last year—being 648 tons more than in 1886; but the sales only realized 462,364 frs. (£18,494), or 348,978 frs. (£13,959) less than before. The average return for tar was at the rate of 32 frs. 50c., or about 26s. per ton. The practice of utilizing this residual for the heating of the retorts has been again resorted to, with the view of turning it to the most profitable account. The market for ammoniacal liquor was also weak; but, as contracts were running, the prices obtained for it were the same as in the preceding year. Altogether, 27,039 tons of liquor were produced, which realized 490,081 frs. (£19,603); being 2164 tons and 38,271 frs. (£1531) more than before.

Owing to the extended consumption of gas, caused by the erection of additional houses, the manufacturing plant at the gas-works had to be increased to the extent of 15 per cent. The results of the year's working were, on the whole, favourable; and, after paying interest and spending a sum of 518,812 frs. (£20,752) in extending the works, the Municipality made a net profit of 5,735,951 frs. (£229,438). In addition to this, account should be taken of the cost of the gas supplied to the public lamps (for which no charge is made), which represents, reckoning the price at 16.9c. per cubic metre, or 4s. 10d. per 1000 cubic feet, a saving to the city of 1,766,144 frs. (£70,646). So that the Municipality realized by the gas undertaking a total return of 8,083,907 frs. (£323,356). The capital employed in the supply of gas in Berlin at the close of last year was 51,836,059 frs. (£2,073,442), which works out to 62c. and 69c. respectively per cubic metre of gas made and sold.

BURY CORPORATION GAS SUPPLY.

SUCCESSFUL WORKING AND INCREASED CONSUMPTION.

Last Thursday afternoon, the members of the Bury Town Council, at the invitation of the Gas Committee, paid their annual visit to the gas-works at Elton. The party were conducted through the works by Mr. Alderman Burrows and Mr. W. Woodward, the Gas Engineer and Manager; and considerable interest was taken in the inspection. In the course of some speeches made subsequent to the visit, Mr. Alderman Burrows referred to the success which had attended the manufacture of sulphate of ammonia since the works for that purpose were established two years ago. Latterly the Committee had, he said, had under consideration the question of the distillation of tar; and a deputation had visited several other works to inspect the various processes for utilizing residuals and obtain information. They had not completed their labours; but what they had seen had borne out the statement which the Gas Manager had placed before them as to the profitableness of undertaking the distillation of tar and of otherwise utilizing their residuals, instead of selling them in the form they were doing at the present time. He had no doubt that if they adopted the process of distilling tar as they saw it carried out at Leicester and Beckton—the

latter was perhaps too large a works to be compared with Bury, but even as it was now done at Leicester—it would be a good thing for Bury. When at Leicester he found from the report presented by the Gas Committee to the Town Council, that from the manufacture of sulphate and the distillation of tar they had made a profit of nearly £7000 in six months. Leicester was about three times the size of Bury; and if Leicester could make a profit of £6000 a year on the distillation of tar alone, it would be a good thing for Bury to take it up. Before, however, they attempted to do anything in this direction the Committee wished to see other places of a similar size to Bury, and then would make their report to the Council. Bury stood in the proud position of manufacturing and distributing gas at a lower price than any other town in Lancashire, and the profitable manner in which their gas-works were carried on was referred to every week, by some corporation or another. This being the case, he thought the Corporation and the Gas Committee were entitled to feel proud of the position they held with regard to that portion of their undertakings. Mr. Woodward, referring to the condition of the works, said the stack of retorts last erected was not perhaps what it would have been if the Committee had had a larger area to build upon. However, they made 7000 feet of gas per mouthpiece, which was 2000 feet per mouthpiece more than in the old ones; and if the whole of them were built on this principle, they could make 3,700,000 cubic feet of gas per day—equal to an annual consumption of 740 millions. Their present works would meet the requirements of the town for the next 25 years, even with a compound increase of 5 per cent. in the consumption. The new stack of retorts had not cost any more per retort than the old ones did; and when one took into consideration the amount of ironwork for the stage and flooring, and the material required, it was satisfactory that it was built at the right time, when materials were not dear. The sulphate of ammonia works had proved to be a profitable undertaking. They received for the ammoniacal liquor during the year previous to erecting the works £850; and last year, after deducting manufacturing and other charges, no less than £2881. It was gratifying to know that since the reduction in the price of gas an enormous number of meters which had been standing idle for six or seven years had been again brought into use, and the houses supplied with gas. Never since he had been in Bury had there been so many old gas-meters connected; and last week they had had an increase of half a million cubic feet in the consumption of gas. Reference was made to the extended use of gas for cooking and heating purposes; facilities being afforded by the Committee for this by the letting of gas-stoves on hire.

GAS V. ELECTRIC LIGHTING AT LEAMINGTON.

At the Meeting of the Leamington Town Council on Monday last week—the Deputy-Mayor (Mr. Alderman Wackrill) in the chair—the following letter, addressed to the Town Clerk by Mr. W. Cross, Secretary of the Leamington Priors Gas Company, was read:—"Several gentlemen have expressed to me their desire that the Gas Company should light a section of either Warwick Street or Regent Street with improved gas-lamps. I explained to them that the existing lamps are the property of the Corporation—the lighting, cleaning, and extinguishing of which are performed by the Corporation officials; and that the Corporation, as the lighting authority, could require the Gas Company to supply as much gas as they liked. Notwithstanding this explanation, these gentlemen stated that they thought it very desirable the Gas Company should make such a proposition to the Corporation. I therefore beg to say that my Company are willing to light the section of Warwick Street between Russell Street and Clarendon Street with improved lamps, if the Corporation are willing to pay for the gas consumed, which it is estimated would be about 131 per cent. more than is consumed by the existing lamps; the estimate being based upon a consumption of 15 feet per hour prior to 11 p.m., and 5 cubic feet per hour after 11 p.m.; the lamps to be provided by, and to remain the property of the Company, and to be lighted and extinguished, &c., by the Corporation officials." The Clerk (Mr. H. C. Passman) explained that the Company were putting the Corporation on the same terms as the Corporation had placed the Electric Lighting Company, so that the Council might judge between the two lights. Alderman Gilbert moved that the letter be deferred until the report of the General Purposes Committee came on; but an amendment was proposed that the letter be referred to the Lighting Committee. Mr. White said he was glad to hear the letter from the Gas Company read. It was only fair to the Company that the Council should put them on the same terms as those granted to the suppliers of the electric light. He contended that the Council had given the Electric Lighting Company 100 per cent. premium, and they were paying double what they previously paid for gas. He was anxious to see that the Gas Company had fair play, and moved as a further amendment—"That this Council accept the terms of the letter from the Gas Company." He trusted that the amendment would be accepted in fairness to the Company. Mr. Burgis said, in order that the Company might have fair play, he would second the proposition. Mr. Purser supported the proposal to refer the letter to the Lighting Committee; saying that the Gas Company should be put on an equality with the Electric Light Company. He pointed out that the electric light had cost 131 instead of 100 per cent. more than the gas. The letter was then referred to the Lighting Committee. Subsequently, the letter received from the Midland Electric Light and Power Company, making an offer to improve their lighting, as stated in the JOURNAL last week, by the fitting up of four arc lamps, five 300-candle incandescent lamps, and twenty-five 50-candle power lamps upon the Parade, at a cost of £33, of which the contractors were willing to pay one-third, and supply the current without extra charge, was submitted; and, after some discussion, the offer was accepted.

SAN PAULO GAS COMPANY, LIMITED.—The report of the Directors of this Company, made up to June 30 last, announces the payment, on the 20th inst., of an interim dividend at the rate of 10 per cent. per annum, free of income-tax; £2000 being placed to an account for the equalization of freights, and £831 carried forward.

THE SHEFFIELD CORPORATION AND THE HANDSWORTH WATER SUPPLY.—The Sheffield Town Council, at their meeting last Wednesday, were asked to approve of an application to the Local Government Board for sanction to an arrangement entered into between the Corporation and the Handsworth Local Board respecting the water supply to that place. The Town Clerk (Mr. Pye-Smith) explained that the Handsworth Board had agreed to purchase water in bulk from the Council. At present the Local Board could not charge any rates beyond the ordinary rates of the Corporation; and they wanted to be in a position to compel the ratepayers to take water, and for the Board to charge their own prices. The three conditions were: (1) That the Handsworth Board should allow the Corporation to lay pipes through their district under their existing powers; (2) that they should take water as heretofore, and as now, from the Sheffield Corporation; and (3) pay the costs of the application and getting legislative sanction to it. The application was agreed to.

* The French ton (2204 lbs.) is meant in all cases in this article.—Ed. J. G. L.

THE ELECTRIC LIGHTING EXPERIMENT AT BARNET.

The experiment in electric lighting which is now going on at Barnes has attracted considerable attention, owing to certain occurrences which have probably not been productive of pleasure to the promoters of the scheme. Readers of our "Electric Lighting Memoranda" have been made acquainted with the mishaps which have attended the project; though the general press has been remarkably silent on the matter. In reference to the last failure of the light (on the 21st ult.), the contractor for the lighting has written to the local paper, stating that duplicate sets of machinery have been completed, and are expected to be soon at work; and that meanwhile he would continue to do his best with the present "temporary" appliances, which he says were erected under the difficult circumstances of "limited time, hurried work, and novel description of arrangements and fittings." Barnet (he adds) is the first town in the United Kingdom whose streets are being entirely lighted with electricity; and the inhabitants should not therefore at the outset look for complete success which he promises is not far distant. Promises, however, are one thing, and performances another. This is forcibly illustrated by a resident, calling himself "Didimus," who has sent to the paper in question a comparative statement of the promises and performances of the contractor. He says: "Some eight or nine months ago Barnet was offered the electric light, and accepted it with a readiness which must have surprised even the enterprising electrician who made the offer. In price it was to be wondrous cheap, and in effect it was to excel. Well, after almost interminable delay, we got the light, and accepted in good faith the promise of the contractor to make it a success; but how about the fulfilment of the promise? What the contractor promised has been recorded in the published reports of the Barnet Local Board meetings; and, for convenience in reference, they have been arranged below in the form of a debtor and creditor account, which my readers may balance for themselves:—

Dr. As Promised by Contractor.

We should have duplicates and storage batteries to meet every possible condition. When the engine stops, there will be a supply to draw upon.

I should give you a system perfectly free from liability to accident.

You would get more light for money, and better light.

The lamps will be 32-candle power.

With 32-candle electric lamps, half the number of the present gas-lamps (104) will suffice to light the town.

Of course, in taking a contract like the lighting of Barnet, I am backed up by good people.

The thing will be a grand success.

A glance at this account shows that the contractor has not very much to his credit so far; and I turn to the prospectus of the Barnet and District Electric Supply Company, Limited, in the hope of finding something to make up the balance. In my search I find the following paragraph:—"The lighting of the public streets of Barnet has been in operation since Sept. 1, with sufficient surplus power for about 100 lights to adjoining dwelling-houses and shops." Where is it? This surplus power must be the outcome of a little miscalculation on the part of somebody, for the paragraph reads like a joke to those who draw their inferences from actual results as shown in the lighting of our streets. A timely exhibition of lighting power, instead of a vague assurance of surplus power, might have redeemed the experiment from failure, and would even now do something towards encouraging public confidence in a venture which hitherto has had so little to recommend it. The electric light will be adopted when electricians can give a successful light at a reasonable cost, and not till then."

Our readers are aware that the adoption of electric lighting for the public thoroughfares has been engaging the attention of the Blyth and Cowpen Local Board—and of the inhabitants, too, as shown by the demonstration recently reported in our columns. The *Blyth Examiner* has disapproved the scheme; and has not lost an opportunity of citing Barnet as an instance of the troubles likely to be brought upon a local authority, and those whom they represent, by trusting to a new illuminant for the lighting of their streets. A representative of the above-named paper recently visited Barnet, for the purpose, as he says, of "forming an accurate estimate of the new-fangled light." Barnet, he tells his readers, is "the only town in the kingdom . . . which has the astounding audacity to dispense entirely with a well-known, well-tried, and generally effective and economical street-lighting appliance in the shape of ordinary coal gas, for a purely speculative alternative." He then goes on to say that he chose Sunday evening for his visit, thinking that then all shops and the like would be closed, and that "the electric lights would have the field entirely to themselves, unaided by the gas consumed by private individuals." But he did not find this to be so, and had to make the best he could of the conditions. We will give the rest of his story in his own words:—

"As I emerged from the station I found myself surrounded by a good light; but I saw at once that these were the ordinary station gas-lamps. The Railway Company at Barnet are evidently not in a hurry to run after the Local Board's electric fad. If the Board choose to spend the ratepayers' money in demonstrating (if ever they should succeed in doing that) the superiority of electricity over gas, the Railway Company will clearly let them go on and do so. They can at any time avail themselves of the dearly-bought experiences of the Board, without involving themselves in any initial or trial expenses. Passing out of the station enclosure on to the top of the embankment, I soon came up to the first electric lamp in the direction of the town. There are two (perhaps three) rather better lights than the generality hereabout; and there seemed to be six or eight of the stronger lights in various parts of the town. There is one near the church, another upon the right-hand side of the street, set back the depth of a house, and in close proximity to a shop, the owner of which will no doubt consider himself rather favoured in having a light placed so near his premises, although it is quite true it stands alongside the disused gas-pillar. There is another on the opposite side of the street, at the junction of a road, near what might be a public pump or pant, from what I could make out in the dark (?). Upon this electric pillar was suspended an oil-lamp—to be fallen back upon when electricity took the sulks. And at the north end of the town, opposite the horse-pond, is another of these rather better lamps. These were, however, exceptional lamps; and even they were shabby enough, in all conscience. The great bulk of the lamps are the most pitiful apologies in the world for public street lights; and I do not wonder that a correspondent in the *Barnet Press* should have said 'If the Gas Company did not light Barnet better than this, then it must have been badly lighted indeed.' Nothing, I think, could very well be worse as a means of street lighting."

As We Find It.

No duplicates and no storage. When the engine slows down, the light follows suit; when it stops, the lamps pop out.

In the space of a month the system has totally failed on two occasions; and there have been many minor failures.

We have less light; the general effect is indifferent; and the cost is much greater than with gas.

They are nothing like it.

We have 73 electric lamps, and this number is quite inadequate.

A Company has been registered, and exists on paper; but proof is lacking that the capital has been subscribed.

It has, so far, been more or less a failure.

"Just after entering the town, the police station is passed on the right hand, and over the door is a bracket with the ordinary gas-lamp. The police authorities seem to provide this lamp; and the gas-light is continued by them. This light is equal to the best electric lamp in the town, and superior to the great bulk of them; and yet it is only an ordinary fish-tail jet, burning $\frac{1}{4}$ to 5 cubic feet of gas per hour, and of an illuminating power not exceeding 15 to 16 candles. Up the street I noticed one of the drink-shops had introduced electricity, while higher up on the opposite side, I think, to this one—another drink-place showed gas; and the latter had a superior light to the former. When I got to the last electric lamp at the north end of the town, I proceeded forward to the next light, which was a gas-lamp; and so marking, I judged, the end of the Local Board district. Between this and the next gas-lamp, still going northward, I stopped about 100 yards—this distance being apparently left to admit of an intermediate lamp being placed some day on the opposite side of the road; and yet the footroad between these two lamps 100 yards apart was as well lighted as the distance between two of the ordinary electric lamps in the town placed certainly not more than about 60 yards apart. The lamps are what are known as the incandescent lamp, as distinguished from the arc lamp. The latter is the lamp of intense brilliancy, dazzling the eye of anyone attempting to look steadily at it, and casting a bluish, unearthly sort of light all round. It is usually screened with opal glass to prevent injury to the eye of the observer. The incandescent lamp, on the other hand, emulates a gas-light as much as possible; and the nearer it approaches to gas the greater its excellence. Hence in the hotel in London where I am staying, we have the incandescent light, and it is not unpleasant; but the modification suitable for indoor purposes, if applied to outdoor purposes, would apparently utterly destroy the chances of the light being at all adopted for street purposes. Hence the Barnet lamps, although incandescent, are not screened or modified in any way. They have all the objectionable and injurious star-like brilliancy of the arc lamp about them, but they are destitute of the illuminating and diffusive power of the arc lamp; so that, as a rule, away from the foot of the lamp, the light they give is miserable in the extreme."

"The streets of Barnet have any number of metal pillars standing in them at the present time; and one would almost fancy that the place was famed for the production of such articles, and that the pillars one sees in the streets are samples from which intending purchasers can make their choice. These are the disused and despised gas-pillars. By the side of them in most of the cases stand the new electric-lamp pillars; and, independent of these, another series of pillars carrying the wires to supply the electricity, while here and there may be seen a Bray—or similar—pillar and lamp, also disused. The electric lamps are placed much higher than the gas-lamps were. Two reasons may have prompted this—one, to keep the wires as far as possible out of the way of the public, and the public by this means out of the way of danger; and the other perhaps to give the lamp a better chance of diffusing its light. The latter object, as I have already said, is a decided failure, and with the present appliances cannot be improved. The readers of the *Examiner* will know that £5 8s. per lamp has to be paid for the ordinary electric lamps in the streets of Barnet. I do not hesitate to say that the ordinary gas-lamps in Blyth streets, hitherto charged £2 6s. for by the Gas Company, give, on the average, better results for street-lighting purposes; and I cannot but infer that it must have been the same at Barnet."

By nine o'clock in the evening, the reporter completed his investigations, and started on his return to London. "I was soon seated," he says; "and, in conversation with the passengers, could not learn the why or the wherefore of this electric fiasco at Barnet—for such it most certainly is. I did learn, however, that whereas the Board had allowed the contractor, for convenience and expedition, to carry his wires on pillars, they had now found it was not according 'to the bond,' and they were going to make him take them down again and bury them in the ground, as they had required the Government to do with the telegraph wires. I thought, however, the contractor could still play quits with members of even a 'defuncted' Board; and it is certain that no member of the Barnet Board will get rid for the next six months of any responsibilities he has incurred over this electric lighting merely by 'resigning' his seat. It is very likely we have by no means heard the last of the Barnet Local Board, and the example it has set the kingdom in electric lighting."

At the meeting of the Barnet Local Board last Tuesday, the Lighting Committee brought up a report on the subject of the electric light, and made certain recommendations. After a long discussion, it was decided to consider the report in Committee. The result was that the matter was ordered to stand over for a fortnight.

ANTWERP WATER-WORKS COMPANY.

A Half-Yearly General Meeting of this Company was held last Thursday, at the London Offices, 86, Cannon Street—Mr. C. CREW in the chair.

The SECRETARY *pro tem.* (Mr. W. Conway) read the notice convening the meeting.

The CHAIRMAN said that he must regret their Chairman's (Mr. Horner's) absence. They would remember that at the time of the last meeting he was suffering from a severe illness; and although he had recovered from that, and had been able regularly to attend the Board meetings, he was away from home at the present moment for the benefit of his health. The present meeting was held at the request of the shareholders at the last annual meeting, in order to have a friendly conversation with the Directors, and to ask questions upon the progress of the Company in the half year. The Directors did not propose to submit any resolutions; but it would simply be his duty to enlarge upon the report and to answer inquiries. There were no accounts to be presented, as these were only submitted annually. The Auditors, however, had been to Antwerp to make their usual half-yearly audit; and they had their figures to show the progress of the concern. He was sorry to report that there had been a falling off in the new contracts, as compared with the corresponding half of last year. The new contracts this half year amounted to 204 as against 305 in the first half of 1887. The value of the contracts in the June half of 1887 was £696. This year, taking the increase in existing contracts, which might be considered as new contracts, the value was £564. There was not a great deal of difference, though the average for the past five corresponding half years had been £1136. There was another thing—they must consider that the new contracts had increased really by a further sum of £440, which had been obtained from customers by the fraudulent use of water; so that their accounts would be increased by this amount in future. These new contracts would not affect the present accounts; but the Company would get the full value of them next year. The attention of the Directors was called by their Manager to the fact that there were a large number of small consumers of water in Antwerp; and, in order to compete with the wells and the rain-storage reservoirs which every house is supplied with in Antwerp, it would be necessary either to reduce the tariff or charge by meter. The Directors looked into the thing carefully; and they found they could reduce the tariff, providing these people would take a minimum quantity of water—that was, agreed to pay the Company so much per

quarter whether they used the water or not. They reduced the price from 40s. to 15c. per cubic metre, according to the minimum paid, varying from 100 frs. to 1250 frs. per quarter. The Directors were satisfied with the result. The past half year showed an increase of £600 under this head alone. The income from all sources amounted to £10,036; while in the corresponding period of 1887 it was £9610—being an increase of £426. This required a little explanation. The income from all sources was made up of receipts for water sold, miscellaneous receipts, interest on amount at banks, and supply service. "Supply service" meant the Company putting in pipes to their customers' houses, in order that they might use the water. Although they had made considerable profit from this business since the thing was first started some five years ago, it had been the policy of the Company to encourage local plumbers to do the work. If he analyzed the total receipts, he found that the water receipts had advanced over the past half year by £922; the interest had also slightly increased; but the "supply service" had fallen off by £536. On the other hand, the cost of the supply service had also been reduced by £400. In regard to the expenses in London and Antwerp, the maintenance had cost over the half year about £154 more; the pumping had cost £89 more; and the depreciation of stores, £39 more. With £400 decrease in the supply service and £151 in the London expenses, they had a decrease in the expenses of £269. The net revenue in 1887 was £3554; and in 1888, £4248—being an improvement to the extent of about £700. In their report, the Directors stated that should the second half-year's working be equal to the present, they would be able to pay an increased dividend this year. This was verified by the figures. They had a credit balance of £1630 last year. Assuming they obtained as much revenue from the second half as for the first, they would have a net revenue of £8500. Putting these two amounts together, they would have a sum of £10,130 available for dividend. Last year they paid 2 per cent.; and if they paid 3 per cent. this year they would have a balance of £1130 left. But there was another matter they would have to consider very soon, and that was the question of an amortization fund, which the Directors had not yet touched. However, they had it in their minds to commence such a fund shortly. But if they did start it this year, assuming the net revenue was £10,130, a 2½ per cent. dividend would absorb £7500, which would give them a balance sufficient to meet the £2500 necessary to put by to pay back the capital at the end of the concession. They had saved £130 a year by renewing at 4 per cent. the £13,000 of 5 per cent. debentures which would fall due on Dec. 31 next. There was no doubt that the wet weather had seriously affected the receipts this year; but it was gratifying to find they had saved a great deal of water by a proper system of testing the mains which had been carried out. The quality of the water had been uniformly excellent. The cost of pumping was now 5d. per 1000 gallons, as against 4½d. in 1887; and the price obtained per 1000 gallons was 10½d., compared with 8½d. Taken altogether, he considered the report a very satisfactory one. No questions being asked, the proceedings terminated.

PERTH CORPORATION WATER SUPPLY.

The annual accounts of the Perth Water Commissioners were presented at a meeting of that body on Monday last week. They show an excess of income over expenditure of £251 19s. 6d., which reduces the debit balance at the beginning of the year from £297 8s. 1d. to £45 8s. 7d. The revenue amounted to £5775 19s. 10d., and the expenditure to £5524 0s. 4d. Of the expenditure, £174 13s. 2d. was spent in prospecting in connection with the new water supply. From the balance-sheet it appears that the works are valued at £48,556 10s. 10½d.; while there are other assets amounting to fully £900, and the amount of debt is £31,895 17s. 10d. Lord Provost Whittet, in moving the approval of the Auditor's report of the estimates for the current year, and that the assessments be fixed at the same rates as last year—namely, 8d. and 4d. in the pound in the inner, and 1s. and 6d. in the pound in the outer area—said that it was thought the rates would be equalized at Whitsunday; and that although the expected surplus was put down at £156, the Finance Committee were hopeful that it would be nearer £256. Mr. McCurrach seconded the motion, and it was carried. Mr. Shaw asked what provision had been made for giving Mr. Leslie, C.E., of Edinburgh, who was to visit Perth, information in regard to the proposed auxiliary supply (to which reference was made by our Edinburgh Correspondent last week). The Lord Provost said Mr. Peattie's plans and report would be submitted to Mr. Leslie, and that the proper thing for the Commission to do would be to allow that gentleman, without any interference, to obtain all the information he could from the proper authorities.

PROJECTED EXTENSION OF THE SWINDON WATER-WORKS

An Extraordinary General Meeting of the Swindon Water Company was recently held for the purpose of sanctioning an increase of capital to the extent of £9000, for the purpose of carrying out additional works. The Chairman of the Company (Mr. W. A. Barns) presided, and explained that for a very long time the Directors had been aware of a great difficulty in supplying the district, and especially the new town with water in sufficient quantities to suit the convenience of their customers; and as long ago as 1836 their Engineer (Mr. Shopland) was asked to prepare a scheme to overcome the difficulty. He suggested that a new 12-inch main should be laid, in addition to the existing 8-inch main, from Wroughton to Kingshill, there to deliver the water into a service reservoir to hold 500,000 gallons. This main would be capable of discharging daily 900,000 gallons of water, from the top water-level of the storage reservoir at Wroughton. He further advised that a new main should be put down to New Swindon capable of supplying 250,000 gallons daily; this being absolutely necessary, since a heavy draught of water was needed. From the service reservoir at Kingshill, it was proposed under the scheme to pump water into a tank for the supply of Old Swindon. If these alterations were carried out, the two districts would have distinct mains and a service reservoir each—both being specially adapted to the districts within their service. The cost of these alterations was estimated at £8280, which included £1620 for a new service reservoir, £2000 for a main to New Swindon, and £4000 for the new main to Kingshill. It was decided that the capital of the Company should be increased by the issue of £1 shares, to be offered to the existing shareholders *pro rata*, at par.

TARAPACA WATER COMPANY.—According to the *Financial News*, the Municipality of Iquique, acting upon reports presented to them by a Committee recently appointed to investigate the water supply of the city, have passed a resolution declaring that, in their opinion the concessions granted by Mr. T. Hart under Acts passed in January, 1885, and February, 1886, "have now lapsed and are forfeit." Our contemporary states that memorials from all the parties interested were received; and before recommending the Municipality to come to the conclusion above recorded, the Committee consulted the Intende of the province, who in turn referred to the Senate. Thus every step was taken to make certain of the facts; and, after these precautions, the Municipality decided against the validity of the concession, which is the principal asset of the Tarapaca Water Company.

LEEDS CORPORATION WATER SUPPLY.

BRADFORD AND THE NIDD WATERSHED.

At the Meeting of the Leeds Town Council last Thursday, the Chairman of the Water Committee (Mr. Alderman Woodhouse) moved—"That the corporate common seal be affixed to a deed of covenant with the Corporation of Bradford, for the purpose of carrying into effect the arrangement made with them as to the rights and interests of the Corporations of Leeds and Bradford respectively in the watersheds of the Rivers Burn, Laver, and Nidd." In doing so, he reviewed the proceedings which had resulted in an amicable settlement of the dispute between the two Corporations. He reminded the Council that, in 1866, Mr. Filliter, who was then the Water Engineer, prepared a report, in which he dealt very fully with the water supply of Leeds. In that report three rivers were mentioned—the Nidd, the Laver, and the Burn. The Nidd, with an area of 32 square miles, gave 21 million gallons a day of water; the Burn, with 23 square miles, and the Laver, with an area of 9 square miles, furnished together 21 million gallons a day; and these numbers, added to the supply from the Washburn to the extent of 23 million gallons a day, would give a total supply to Leeds of 65 million gallons of water daily. That this would be the future supply of Leeds had come to be regarded as a "pious legend," until Bradford, which used to get its water from the lower reaches of the Wharfe, found, on extending its search for more water, that the water was too hard for its manufactures. In 1887 Bradford therefore applied to Parliament for powers to secure the waters of the River Burn and its tributaries. The Leeds Water Committee found it necessary to take action; and, after some correspondence, an amicable arrangement had been come to—the consideration being that Leeds would not oppose Bradford in the event of that town making application to utilize the waters of the Nidd; while when Leeds had to go to Parliament for power to extend the water supply, it might make application for the Burn and its tributaries, and Bradford would not place any obstacle in the way. The motion was agreed to.

FINDING WATER BY DIVINATION.

The *Colchester Mercury* for last Friday contained the following account of a successful experiment in the use of the divining-rod in searching for water:—

"On Thursday, the 27th of September, Sir Henry Selwin Ibbetson and Lady Selwin Ibbetson invited a party of ladies and gentlemen to witness the performance of a Mr. Lawrence, from the West of England, with the divining-rod; the object being to test whether he would be able by its means to discover water on the Down Hall Estate. The party were first invited to lunch and chat with the expert, who is an old gentleman 79 years of age. Mr. Lawrence first walked round a well near the Hall to ascertain which way the water took its course; and as soon as he arrived at the opposite side of the well, he was seized apparently with convulsions. There were many exclamations of surprise from the company; and Sir Henry Selwin Ibbetson said, 'That's very satisfactory and conclusive, as we know the water takes that course from the side of the well down towards the wood and the brook.' With this astonishing revelation of the power possessed by Mr. Lawrence, the party proceeded to the kitchen garden, where her ladyship said she should like to find water. After the expert had made a couple of rounds, he came upon a vein of water, which was ultimately traced coming from the well across the land over sand towards the wood. Mr. Lawrence then tried in the yard next the dairy, and at once came upon two or three places where he stated water was to be found. One of these was under the doorstep; and while the party were conversing together, the expert was having one of his little dancing games upon the step of the back door. A field was afterwards tried. The expert, in company with one of the guests (Mr. Sam Deards), walked the field with Mr. King, the bailiff, and a man or two to drive stakes at every exhibition of the violent shaking of the divining-rod. In three instances Mr. Lawrence was so overcome that he literally fell into the arms of Mr. Deards for support. Having traced one spring running right across this field, the party proceeded to another field, where Mr. Lawrence was again seized with a shaking fit. At the lodge, where a well was very much wanted, the expert discovered a good spot right in the centre of the back yard. A more suitable place could not have been desired. A trial was next made at Besses Lodge; and here it was that one of the most marvellous displays occurred. Mr. Lawrence proceeded to walk round in the path of the garden, and had gone three-fourths of the way when he was seized with one of his 'fantastic tricks.' Mr. Lawrence afterwards stood over the soft-water tank; but this had no effect whatever upon him—still water having no power over the divining-rod. Going into the corner of a large hilly field opposite the lodge gate, water was again discovered; the expert and rod being violently affected, so much so that Mr. Deards caught hold of one end of the stick, and yet it moved and twisted in his hands. Mr. Lawrence asked Mr. Deards to stand behind him and take firm hold of his wrists. Mr. Deards expecting to receive a shock, caught hold of both wrists and held them firmly, but could not keep them from violently shaking. Water was discovered in other places, and the party then returned to the mansion. Sir Henry mentioned how delighted and amused he had been at having made Mr. Lawrence's acquaintance. Before leaving, Mr. Deards asked Mr. Lawrence to give to the *employés* of the estate and house one more proof of his evil spirit; and he did so—going at once to the doorstep of the mansion, and also to one of the stakes driven down near the garden gate. The effect that Mr. Lawrence's performance produced upon the minds and faces of some of the spectators was really most amusing."

We learn from a West of England paper that Mr. Mullins, whose recent experiments at Hastings have been noticed in the *JOURNAL*, is now carrying out a trial near Cirencester, under circumstances of great interest. Mr. J. Hayward, of Barnton Mill, occupies a field, barn, and some land in the adjacent parish of Bagendon; and at buildings called Price's Barn there is no water supply, except the runnings from the roofs. The buildings stand on the summit of the rolling Cotswold district; the ground being 144 feet above the road from Cirencester to Cheltenham, which runs along the valley of the Churn close by. Hearing of Mullins through a relative, Mr. Hayward, with the permission of his landlord, invoked the aid of the "diviner." About three months ago, Mullins, with a hazel twig, walked over the paddock in front of the buildings, and the rapid revolution of the twig in his hand at certain spots indicated, he asserted, the line of a spring running through the hill into the valley of the Churn below. After an interview with the landlord of the property, Mullins undertook to sink a well—the depth he estimated as necessary being from 70 to 80 feet—whereas owners of house property in the vicinity situated on much lower levels have sunk from 120 to 150 feet, and then often failed to keep a supply of water in dry weather. By the terms of the contract, Mullins is to receive a certain stated sum on finding a supply of water; but if he fails he does not receive any payment whatever. His men have now been at work for seven or eight weeks, and have sunk just over 70 feet through the rock without coming to water, but they do not entertain any anxiety as to the result. The termination of the undertaking is being looked forward to with interest.

NOTES FROM SCOTLAND.

(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, *Saturday*.

Although this year we have not the excitement of a gas transfer in the impending municipal elections, the subject is cropping up here and there. It is brought up by those who took part in the business as a means of reflecting credit upon them for their part in the work; and it is referred to by new candidates in that conveniently mysterious way which, on investigation, may mean anything or nothing, but which at first sight conveys the impression that the speaker, if he had been in power, would have done it much better. A fine instance of the latter was given on Tuesday night, when an aspiring candidate told his hearers that "the gas purchase, he thought, had been too dear. The Trust must be very economically administered; and he would begin by abolishing the charge for meters." He went on to say that the principal streets should be lighted with electricity. Was ever such bunkum talked? If he means by economy the judicious management of the business in the interests of the community, why did he recommend costly experimenting in electric lighting? If he meant that the gas undertakings had cost so much that they must be managed so as to maintain a large revenue, why did he suggest that the sum at present derived from meters should be thrown away? Were his advice adopted, the revenue of the Gas Committee would be reduced by the charge for meters, and the citizens have, in addition, to be taxed to maintain electric lighting in one or two thoroughfares. Economical management would scarcely be a correct description of that sort of thing, I fancy.

The proposal to spend £20,000 upon the improvement of the Edinburgh Gas-Works, which I mentioned a fortnight ago, has been the subject of newspaper correspondence here. One of the writers is Mr. John Romans, C.E., who, it may be remembered, strongly opposed last year the transfer of the Edinburgh works, averring that it was possible to build and equip new works with mains and services for £300,000. Mr. Romans observed the statement in the *JOURNAL*, and wonders why it did not appear in any Edinburgh newspaper. He then goes on to say that, instead of being alarmed at the amount asked for, his surprise, if any, was as to how the Engineer had managed to circumscribe his requirements to that figure. His opinion remains unchanged that the Commissioners should not spend a shilling upon the Edinburgh works, but set honestly to work to obtain a site for new works near to coalfields, of easy railway access, not sightable from the topmast of a man-of-war, and there gradually erect the city gas-works complete. He concludes: "Of course, this will be a bitter pill to swallow for the professional men who were the deceivers, and the town councillors who were deceived. Still it is better to face it, as to this it must come, if gas is to continue to be our chief illuminant for the next quarter of a century." Mr. Romans is a little impetuous, as the strength of his language shows. If he cannot understand how Mr. Mitchell's proposal was to expend only £20,000, might I point out to him that, with the surplus power of the Leith gas-works, a full output will not be required from the Edinburgh works, and only a portion of them need be dealt with in the meantime. The same reason also militates against his recommendation to procure a new site at once. Until the Leith establishment gets worked out, there is no necessity for superseding it. This may be twelve years hence; so that there is time to look out for a new site, and meantime I am not convinced that it is not the best policy of the Commissioners to expend a moderate sum upon the improvement of the Edinburgh works. This course would enable them to make the most of both the existing works; and then, after the costs incident to a transfer have been at least partly met, the Commissioners would have more freedom in recommending the large outlay involved in the erection of new works.

The Arbroath Gas Corporation have changed front on the question of extending their works. Only a month ago, they resolved to proceed with the improvement of the existing works, and the erection of a new holder for the lower district of the town. The alternative proposal, to entirely remove the works, and build them on a lower site, was then flouted by Provost Anderson as "far too late." At their meeting on Monday, instead of giving authority for the work to go on, they had a long discussion, and then appointed a Special Committee to look out for a suitable site for new works; and the question of the proposed extension was remitted to Mr. W. Foulis, Engineer of the Glasgow Gas-Works, to consider and report upon. The Corporation already possess a report by Mr. K. Mitchell, of the Edinburgh Gas-Works, on the subject. Their remit to Mr. Foulis looks very much like this—that, having changed their minds, they are anxious to get the opinion of a man of skill to back them up. The position to which they have gravitated appears to be that, as an expenditure of more than £5000 in extensions is inevitable, as new works could be more economically worked than the present, and as almost as much would be obtained for the present site as would procure a new one, therefore the cost of transferring the works to a new site is the only item which stands in the way of their having new works. There would be a saving of £300 a year on cartage alone, if the new works were placed beside the railway; and that, with other economies, it is estimated, would more than meet interest on the cost of the transfer. All this is very fine in theory. Whether it can be put in practice, the Corporation knows as well as anybody depends entirely upon cost, and chiefly upon the cost of a new site. Why, in these circumstances, they should want further speculative reporting is not apparent. A remit to obtain a site, and to ascertain its price, would have been sufficient. After that, if the price were suitable, inquiry could have been made as to the one point of what the cost of transfer would be; and the whole question could then have been taken up by the Corporation, and decided without difficulty. It may appear more heroic to breast the question at once, and have a report upon "the whole subject;" but, to my mind, it is not likely to be either the most intelligent or the most profitable.

Mr. Adam Pratt, of Aberdeen, who may be said to be the backbone of the agitation there in regard to alleged overcharges for gas, keeps pegging away at the subject with untiring zeal. He must be a veritable thorn in the side of the gas management in Aberdeen. He seems to be in almost constant correspondence with them; and scarcely a week passes in which he does not take advantage of the columns of the local press to let the world know what has taken place. This week a letter by Mr. Pratt to the Town Clerk is published, which indicates a more serious attitude than has yet been taken up by the Gas Committee towards the complaining party. Mr. Pratt writes: "With reference to the overcharged accounts of 134 gas consumers, as furnished to you on the 9th of August last, as requested, would you kindly inform me if the oases in detail have yet been investigated? Complainers on the list, whose gas supply is cut off, have received notice from the Gas Treasurer that legal proceedings are to be taken against them." From this it would appear that the Committee have made up their minds to have no dallying on the subject of liability for what has been already incurred; and from this it is easy to infer that they have investigated all the accounts in respect to which there were complaints. It should not be a difficult task to inquire into 134 cases. I have been informed by a resident in Aberdeen that some of those who complained have received a reduction, presumably where the meter was found

to be at fault—a situation out of which the Gas Committee could not get except by remitting a portion of the sum charged.

At the recent annual meeting of the Newport (Fifeshire) Gas Company, it was resolved, on account of the improved financial position of the Company, to reduce the price of gas 5d. per 1000 cubic feet.

At the meeting of the Fraserburgh Police Commission last Monday, it was proposed that a Committee be appointed to confer with the local Gas Company, with the view of arranging for a voluntary transfer of the Company's undertaking to the Commission; but, after discussion, it was resolved to take no further steps in the matter in the meantime.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, *Saturday*.

When the Glasgow Corporation Gas Committee's minutes were up for consideration at the usual meeting of the Town Council on Thursday, attention was drawn by Treasurer Richmond to the fact that a number of contracts had been entered into for the extension of the Tradeston Gas-Works. While admitting that he had the greatest confidence in the Gas Committee, he thought the Council should know the nature of the contracts referred to, and what was being done, seeing that an expenditure of £150,000 or £160,000 was involved. Mr. Ure, Convener of the Sub-Committee on Works, said that they would be glad to exhibit the plans, and give all the information desired. Bailie McLaren stated that about a year ago the Council had under consideration the extension of the Tradeston works, and at that time plans and specifications were submitted, and the probable expenditure was sanctioned; so that the work which the Council had already approved of was what the Gas Committee were carrying out. They had nothing to hide, and would be glad to submit the plans of the alterations and extensions resolved upon.

Several of the Glasgow Town Councillors have touched upon gas affairs at the annual meetings of the electors held in their respective wards this week. Bailie Mitchell spoke of the Gas Trust as being in a very prosperous state, as was evident by the fact that 2d. per 1000 feet had been taken off the price of gas—from 2s. 10d. to 2s. 8d.; and in view of the possibility of the annexation of the suburban burghs and adjacent districts to the city, the Gas Committee had agreed, he said, to recommend to the Town Council to buy the Partick, Hillhead, and Maryhill Gas Company's works. Of course, if there was no annexation, there would be no purchase. Bailie Stevenson, in the Fifteenth Ward, stated that the Gas Trust revenue for last year was somewhere about £383,000; and they had put aside £49,000 for depreciation. One of the representatives of the Twelfth Ward (Mr. J. Macfarlane) affirmed that the reduction in price amounted to a sum of £60,000; and this saving to the gas consumers had been effected without any material lowering of the quality of the gas. Bailie McLaren, in the course of a speech which he made on Thursday at a meeting of his constituents in the Fourth Ward, stated that the revenue of the Police and Gas Departments alone amounted nearly to that of some of the small German principalities; and the Convener (in this case himself) had nearly as much to do as some of the Chancellors of those principalities in endeavouring to bring in a budget calculated to keep down the rates. Referring to the reduction that had been made in the price of gas, he said he had anticipated that it would be followed by a further and similar reduction next year; for they had purchased about 290,000 tons of coal at a little less than the average price paid last year, and with the increased consumption and better gas-producing appliances, they might be able to present a very favourable balance-sheet when the extension of the city boundaries came before Parliament next session. He also remarked on the complaints which he had heard to the effect that, while the price of gas was reduced, the accounts of the consumers were always the same; at all events, they did not get lower. He had himself made a test in regard to this matter; and the result he found was that, while ten years ago the Public Lighting Department consumed 146 million cubic feet of gas, and paid £29,375, during the past year the consumption was 190 million cubic feet, for which the charge paid was only £25,460.

A public meeting was held in Stevenston (Ayrshire) last Monday, for the purpose of further considering the proposal to form a new Gas Company, to manufacture gas from oil. Mr. S. Lyon, who presided, reported that shares had been freely taken up on the station side of the town, and that the residents in other districts in which the shares had not been so well taken up had promised to patronize the new Company. Mr. Kerr, of Ardeer Foundry, the principal mover in the scheme, submitted plans and the estimated cost of the proposed oil-gas works. In the course of the conversation which ensued, it was suggested that in the meantime small works should be started, of sufficient producing power to meet the demands of New Street and the district around the Railway Station. Ultimately, it was agreed, on the motion of Mr. Pennel, seconded by Mr. Rickett, that, before deciding on the erection of new gas-works, a deputation should be appointed from the meeting to wait upon the Directors of the existing Gas Company, and urge the propriety of reducing the price of gas to 4s. 6d. per 1000 cubic feet, and to report to a future meeting. From this result of Monday's meeting, it is very evident that the proposal in question has not met with anything like enthusiastic support.

At the monthly meeting of the Millport Police Commissioners last Monday, a communication was submitted from the Gas Company, stating that the price of gas supplied to the public lamps would be 5s. 10d. per 1000 cubic feet, and that an allowance of 5 per cent. would be made on payment of the account.

At the meeting of the Armadale Police Commissioners on Monday, the charge for gas consumed in the public lamps was also under consideration. A letter from the Gas Company was submitted in which the Commissioners were requested to sign an agreement to the effect that they pay 10s. for each gas-lamp for one year; that a reduction of 1s. be made on each lamp, seeing that there had been no lighting during September; further, that the lamps be lighted at dusk and extinguished at ten o'clock every night except Saturdays, when it should be done at eleven o'clock. If extra light were needed during the night for street alterations, &c., the Commissioners should pay for the same accordingly. The Clerk was empowered to make several alterations in the terms of the proposed contract, failing the acceptance of which by the Gas Company the Commissioners decline to sign the agreement.

The Dunblane Burgh Commissioners have approved of an offer from the local Gas Company to supply gas to the public lamps at 5s. 10d. per 1000 feet, with a discount of 30 per cent.

That part of the burgh of Wishaw known as Craigneuk was again before the Commissioners last Monday in regard to the proposal to light the public thoroughfares with oil. A report on the subject was read to the meeting, which had been prepared by the Burgh Surveyor, Mr. Tait. It stated that, to light Craigneuk and district with oil-lamps in anything like an efficient manner, the distance between each lamp should not be more than 100 yards. To do this 30 lamps would be required. The first cost of the lamps, which could be used for gas, would be £79 10s.; lighting, 14s. each per annum, £421; oil, 9s. 6d. each per annum, £14 15s.; repairs, 3s. each per annum, £4 10s.—thus making the annual cost, £39 15s. The report further stated that, with oil at its present price, the lighting would

cost about 25 per cent. less than with gas; but the saving is a long way more than counterbalanced by the extra charge for lighting and cleaning the oil-lamps. Baillie Russell questioned if any other town in Scotland ever made such a ridiculous proposal as that of lighting the streets with oil-lamps. He was in favour of a small Committee being appointed to confer with the proprietors of the Craignuk district to learn how many of them were willing to make connections if a gas-main were laid down, sufficient (say) for 30 lights, the public lamps then, of course to be lighted with gas. A Committee was ultimately appointed for this purpose.

The proposal to form a Water Commission for the burghs of Airdrie and Coatbridge, and various adjacent parishes, is now fully launched before the public throughout the district, and already it has been favourably received. The intention of the proposed Water Commission is to buy up the undertaking of the Airdrie and Coatbridge Water Company. A meeting was held recently, at which all the local authorities of the district were represented, and the matter of buying up the undertaking was fully considered. A discussion took place on the practicability and advantage of the scheme to the wide district interested in it. In the course of conversation, it was stated that the proposed terms of purchase could be either to pay the Water Company the present selling value of their shares, or give them perpetual annuities at the rate of 10 per cent. on their ordinary shares, and 5 or 6 per cent. on their preference shares. On Thursday of last week a special meeting of the Airdrie Town Council was held, in order to receive a report on the subject from the Committee appointed to attend the meeting already referred to. The report recommended the proposed scheme of purchase; and after considerable discussion, the Council agreed to its adoption unanimously. In the event of the Coatbridge Town Council also agreeing to the proposal, it was remitted to a Committee to call a meeting of the ratepayers of Airdrie, so as to have their opinion of the scheme. The matter has yet to be discussed at special meetings of the Shotts, Bothwell, and Old Monklands Local Authorities, and at the Coatbridge Town Council.

The Clydebank Police Commissioners and the tenants of houses on common stairs have got into a very serious difficulty in regard to the lighting of the closes and stairs. At the quarterly meeting of the Commissioners on Monday, the Lighting Committee reported that the Glasgow Gas Corporation required a deposit of £3 from the tenants of each close and stair before they would supply gas for such places. The Clerk stated that he had called at the Gas Office in Glasgow on the subject; but the only abatement he could get was the reduction of the deposit to £2. Mr. Crawford thought the demands of the Gas Trust were unreasonable. When they supplied the gas before with a No. 1 burner, they did so at 12s. 3d. a year. There were only two No. 1 burners in a close; and this at the most was 24s. 6d. a year. How they came to ask £2 or £3 he could not make out. A long conversation took place on the subject; and reference was made to the provisions of the Scotch Police Act bearing upon stair lighting. The result was that the Master of Works was instructed to see that the closes and stairs were lighted, and to institute prosecutions where that was not done.

On the Glasgow Stock Exchange on Wednesday, the ordinary shares of the Partick, Hillhead, and Maryhill Gas Company were sold at 85s. per £5 share; being a reduction of 1s. 6d. from the last price at which business was done.

Sulphate of ammonia has been selling this week at £11 10s. per ton; and there are inquiries for forward delivery.

In the earlier part of this week, the Glasgow pig-iron warrant market was flat; the price of Scotch iron receding to 40s. per ton cash on Tuesday and Thursday. The market closed firmer yesterday, the price for Scotch warrants being 40s. 8d. per ton cash buyers, and for Cleveland and hematite iron 43s. 10½d. and 33s. 11d. respectively. The Scotch special brands are steady.

On the whole the local coal trade continues to be in a very satisfactory position. For certain qualities of coal, there is an active shipping demand; and full prices are maintained at all the export centres. Good house coal now commands 7s. per ton at the pits.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Oct. 13.

Sulphate of Ammonia.—A continued fair prompt demand has kept the market very steady; and there is therefore no change in values to be reported. It now seems probable that present prices will be maintained throughout the month; for although more, and larger, parcels are coming on the market, buyers are found for them, and it is reported that £11 12s. 6d. has been paid for all October delivery. The inquiry for spring contracts also continues; and buyers pay advanced rates for the few contracts which they can pick up. Nitrate on spot has advanced to 9s. 9d. to 10s.; but there is no change in the values of floating cargoes or of parcels for spring delivery.

LONDON, Oct. 13.

Tar Products.—A little more life has infused itself into this market, with the exception of benzols, which are both flat and drooping. Carbolic acid is decidedly better; and there is a fair demand for anthracene. Pitch buyers are now in the market; but they look askance at the higher prices demanded by distillers. Prices may be taken as follows:—Tar, according to position, 17s. 6d. to 22s. 6d. per ton. Benzol, 90 per cent., 3s. per gallon; 50 per cent., 2s. 4½d. Toluol, 1s. 9d. per gallon. Solvent naphtha, 1s. 3d. per gallon. Crude naphtha, 30 per cent., 1s. per gallon. Light oil, 3d. per gallon. Creosote, 2d. per gallon. Pitch, 12s. to 15s. per ton. Carbolic acid (crude), 3s. 4d. per gallon. Cresylic acid, 9d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 6d. per unit; "B" quality, 1s. 3d.

Ammonia Products.—Sulphate is in decidedly good demand, and the price is firmer. The higher price of nitrate of soda is likely to force this product to a better figure. The business of the week is reported at varying prices from £11 8s. 9d. to £11 12s. 6d., less discount. Gas liquor (5° Twaddell), 7s. 6d. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 1½d. per lb. Carbonate of ammonia, 3½d. per lb. Murate of ammonia, brown, £18 per ton; white, £27. Sal-ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, Oct. 13.]

Sulphate of Ammonia.—The sulphate market keeps very firm, though there is no change in the quotations. Business is reported at £11 11s. 3d. to £11 12s. 6d. f.o.b. Hull, and at similar rates at Leith and Liverpool. Beckton is quoted at £11 12s. 6d., and outside makes in the London market are realizing similar figures. The French demand is still good; and there are numerous inquiries for spring delivery.

Tar Products.—Benzols remain without any decided change. If anything, the chances are for the better so far as parcels for early delivery are concerned; 90's may be called 3s., and 50/90's, 2s. 5d., while solvent is still firm at former prices. Anthracene is still unchanged; while crude carbolic has gone a shade stronger. Pitch is stated to be very firm; and the rumour that Beckton has sold some quantity at 15s. has given a little healthier tone to this branch of the tar trade.

REDUCTION OF METER-RENTS BY THE BRISTOL GAS COMPANY.—The decision come to by the Directors of the Bristol Gas Company to reduce their meter-rents nearly 50 per cent. will entail a sacrifice of about £2500 per annum.

SALES OF SHARES.—On Tuesday, the 2nd inst., Mr. Burbidge sold by auction, at Calne, 50 fully-paid £2 shares in the *Calne Water Company, Limited*. The last dividend paid by the Company was 6½ per cent. per annum. The shares were put up in lots of ten each. The bidding for the first lot was started at £2 5s., and advanced to £3 5s., when the shares were knocked down to a resident in Calne, who purchased the remaining lots at the same rate.—Last Tuesday, Messrs. Nicholson, Greaves, and Barber sold at Sheffield, 891 "D." new shares in the *Sheffield Gas Company*. There was a large attendance, and the competition for the shares was keen. Of the entire number, 105 were sold at £4 5s. prem., and 91 at £4 7s. 6d. prem. Nothing had been paid on the shares; indeed, the first call will not be made until next month.—Last Tuesday, Mr. J. P. Chapman sold by auction a number of shares in the *Lewes Water Company*, which realized unusually high prices. The first lot offered was an original fully-paid £25 share, which was sold for £78 10s. to a resident in Lewes, who subsequently purchased a similar share for £77. New shares (£25) fetched £52 10s., £53, and £53 10s. The last lot offered was £20 of preference 5 per cent. stock, which was sold for £30.

THE OIL LIGHTING ON HAM COMMON.—At the last meeting of the Ham Local Board, the following petition was presented:—"We, the undersigned inhabitants of Ham, beg to bring before the notice of the Local Board the very inefficient lighting of Ham Common and the parish in general. We consider it alike dangerous to foot passengers, vehicles, and property; and therefore desire that our parish should be again lighted with gas, and not sunk in the mediæval darkness of oil-lamps. We are quite sure that hardly anyone will object to the small, if any, additional cost of effecting this amelioration." The petition bore the signatures of about 67 persons, and the Chairman (Rev. T. G. P. Hough) said there were not more than a dozen ratepayers amongst them; the signatures were mainly those of poor people who were not ratepayers. In reply to a member, the Clerk said there were 20 lamps in the district; and the cost of lighting the parish last year was £44 6s. 11d. It was agreed that gas would be much better than oil; and one member remarked that on a windy night he had seen the Common with hardly a lamp alight. It was decided that the Clerk should write to the Richmond Gas Company and ask what would be the cost of lighting the lamps for six months, or a longer period.

THE PUBLIC LIGHTING QUESTION AT BLYTH.—On Monday last week a public meeting of the ratepayers of the Cowpen township, Blyth, was held in the Market Place, under the auspices of the Cowpen Local Board, to take into consideration the advisability of lighting the Cowpen township by means of electricity; gas having been abandoned owing to a dispute with the Gas Company. Having heard the estimated cost of lighting by the proposed system and by oil, the meeting unanimously agreed to urge upon the Local Board the advisability of adopting the electric light without further delay.

THE DANGERS OF OIL-LAMPS.—During the last few weeks several of the tradesmen of Oldbury have had their gas cut off, and have been lighting their establishments with oil, which is said to be much cheaper. Some of the members of the Local Board have expressed their fear that this plan would be generally followed; but up to the present it has not been. One evening last week an explosion took place in the window of a tradesman in Church Street, who has been using oil-lamps. One of the lamps burst; blowing out a portion of the window, and setting fire to the materials therein. Fortunately the fire was not of a serious nature.

SELKIRK WATER SUPPLY.—About 21 years ago the old pump-wells in Selkirk were superseded by a filtration and pumping scheme; the water being drawn into a collecting well from a gravelly meadow at the side of the River Ettrick, and pumped up 300 feet into a supply reservoir. Latterly the supply—about 35 gallons per head per day to a population of upwards of 6000—has been found slightly insufficient. The Burgh Surveyor (Mr. J. Priddy) was recently instructed by the Police Commissioners to consider the best means of increasing the supply. Mr. Priddy at once set to work, and has just completed operations; and by cutting drifts in the gravel-bed and digging a second collecting-well, at the cost of about £600, a superabundance of excellent water has been obtained.

KIMBERLEY WATER COMPANY, LIMITED.—The Directors of this Company recommend an interim dividend at the rate of 10 per cent. per annum, free of income-tax, for the half year ending June 30 last. They also announce that a preliminary agreement has been entered into for the acquisition by the Company of the De Beers Consolidated Mines Water Supply Act, recently passed by the Cape Parliament. This purchase, when completed, will put an end to the threatened opposition by the construction of new water-works.

BRISBANE GAS COMPANY.—The report of the Directors of this Company for the half year ending June 30 last states that there was a steady increase in the demand for gas in that period. The sales amounted to £12,309; and this, with the balance brought forward (£9341), made a total of £21,250. The manufacture and distribution of gas cost £7358; rates and taxes amounted to £158; interest to £1890; the reserve fund to £7000; and there was a balance of £4310 at the close of the six months. The Company's new works are fulfilling the expectations of the Directors.

THE BURSTING OF A RESERVOIR IN SOUTH AMERICA.—In the JOURNAL for Aug. 21 last, we briefly recorded a serious disaster which occurred to a reservoir in Valparaiso on the 11th of that month. From particulars since received, we learn that the reservoir was situated 600 feet above the level of the city of San Juan de Dios, the streets of which were deluged. The water rushed through the city in a wave 12 feet high, carrying nearly everything before it. At first it was thought that an immense tidal wave had come from the sea. The shops were flooded, and their contents destroyed. The people who were in the streets at the time were washed up and down—some being drowned, and others sustaining terrible injuries. Four days after the disaster the streets were still in an impassable state. No fewer than 57 dead bodies were recovered up to the time the despatch was sent off; but this number it was thought would be largely increased.

THE QUALITY OF THE LONDON GAS SUPPLY

DURING THE FOUR WEEKS ENDED OCT. 9.

* Station closed during alterations.

SULPHURETTED HYDROGEN.—None on any occasion.

PRESSURE.—In excess on all occasions.

Note.—The standard illuminating power for common gas in the Metropolis is 16 sperm candles, and for cannel gas 20 sperm candles. Sulphur not to exceed 22 grains in 100 cubic feet of gas; ammonia not to exceed 4 grains in 100 cubic feet of gas. Pressure between sunset and midnight to be equal to a column of 1 inch of water; between midnight and sunset, 6-10ths of an inch.

GWYNNE & BEALE'S PATENT GAS EXHAUSTERS AND ENGINES.

PLEASE ADDRESS IN FULL—GWYNNE & CO.,

ADDRESS FOR TELEGRAMS: "GWYNNEGRAM LONDON."

HYDRAULIC AND GAS ENGINEERS, ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C., ENGLAND.

TELEPHONE No. 2698.

Thirty-three Medals at all the Great International Exhibitions have been awarded to GWYNNE & Co. for Gas Exhausters, &c.

Only Medal at the Liverpool International Exhibition, 1886, for Centrifugal Pumping Engines.

They have never sought to make price the chief consideration, but to produce Machinery of the very highest quality.

The result is that in every instance their work is giving the fullest satisfaction.

They have completed Exhausters to the extent of 24,000,000 cubic feet passed per hour, which are giving unqualified satisfaction in work, and can be referred to.

Can be made, when desired, on their New Patent principle to pass Gas without the slightest oscillation or variation in pressure.

NO OTHER MAKER CAN DO THIS.

GAS VALVES, VACUUM GOVERNORS, REGULATORS, PUMPS, &c., &c.

Catalogues and Testimonials on application at the above address.

ONLY 75 REVOLUTIONS PER MINUTE.

The above Engraving shows Two Engines driving Four GWYNNE & CO.'S PATENT NON-FLUCTUATING EXHAUSTERS, to pass 200,000 cubic feet per hour (without the slightest oscillation), at the EFFINGHAM STREET GAS-WORKS, SHEFFIELD.

THE JOURNAL OF GAS LIGHTING, WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, OCTOBER 23, 1888.

COAL OWNERS, MINERS, AND AGENTS.

ONCE more in the newspapers there is talk of coal, in consequence of the imminent conflict between the miners and mine-owners of the great district of which Sheffield is the centre, over the demand of the men for a 10 per cent. increase of wages. The Mayor of Sheffield has tried to mediate between the two parties; but the latest intelligence from the seat of the disturbance is to the effect that the employers have met and decided that the demand of the men must be resisted to the uttermost. If this decision is really acted upon, and if the men are firm, there must inevitably be a strike of great magnitude and far-reaching effects. The price of coal will go up, in consequence of the cessation of the supply from one of the largest producing districts of the country; and then perhaps the demand of the men may be granted, but possibly not until after all the good that might be expected from the concession has been neutralized by the waste of the industrial war. Some observers declare that, not-

withstanding the firm attitude taken up by the coal-owners for the time, they will yield the advance of wages rather than lose their share of the improvement of trade that has been recognized in all parts of the country. Indeed, it is even reported that the advance has been granted by some owners. With reference to this point, it may be at once confessed that the common sentiment of the general public is in favour of the miner receiving his fair share of any advance in national prosperity. It is, of course, natural for wage-earners of every description to keep on the alert for a chance of getting higher pay for their labour, as it is for paymasters to try to get their labour at the cheapest possible rate. There is something in the work of the coal miner, however, that appeals strongly to the sympathies of the rest of the nation; and when miners combine to ask for an advance of wages—say, from 20s. to 22s. a week—alleging that the state of trade warrants such a request, there are few people who would not be glad to hear that they had obtained it. If the price of coal were advanced by 5d. or 6d. per ton, which would more than suffice to give the miner the higher wages he asks for, nobody would have much reason to complain. If gas coal, for example, is made 1s. a ton dearer before the winter actually sets in, gas makers will not be materially affected. We have never in these columns laid excessive stress upon the desirability of extreme cheapness for coal. On the contrary, we have always urged that coal prices should be such as to provide fair wages for the workmen and reasonable profits for their employers, and deplored the competition and other less clear influences of trade that have for many years kept the price of coal down to an unremunerative level. If, therefore, there is in the present aspect of affairs connected with coal mining the germ of a promise of better days for coal-owners and miners, we should welcome it, even though gas coal were made slightly dearer. Coke and tar would then be dearer too; so that the net cost of coal for gas making need not necessarily be enhanced.

The coal trade of the country—or at least that branch of it with which we are most immediately concerned—has long been in a condition that could not be called satisfactory to anybody. Coal-owners, agents—in short, everybody interested in gas coal contracts from the suppliers' side—have complained of the difficulty of making a living out of the ruling prices, and have been accustomed to assume the part of persons aggrieved by acceptance of their own terms. They endeavoured to cut each other's throats, and then wept loudly over the prevalence of the unnatural strife among brethren. No doubt for many years the vast capital sunk in the coal trade has not yielded very much of a return to its possessors. A writer in *The Times*, dealing with the present outlook in the trade, remarks that "in many cases the coal-owners have carried on their business for a number of years without any profits at all;" and this is probably not an exaggeration of the state of affairs. It can at least be said, however, that the coal interest has not suffered in silence. The takers of unremunerative contracts have not been thankful for them, while knowing that they must continue to turn out coal at any price in order to keep their capital from sinking out of sight altogether. It is doubtless a trial to mine-owners, who have thus kept their workmen employed at a loss to themselves, to be met with a demand for higher wages as soon as there is the faintest prospect of making up for lost time; but, in the conflict of selfish interests which rules the industrial world, it is seldom safe to say what claims are just or unjust. All that we are for the present concerned to remark upon the question is that we believe consumers of coal in general can well spare a little more money for it than they have been recently required to pay, and that they will do so willingly, provided that the miner, and the owner likewise, gets his fair share. The outer world will be justly disgusted, however, if it is discovered that the demand of the workman for 10 per cent. more wages is made, by the machinations of middlemen and others, to excuse a great advance in the selling price of the delivered commodity, or to create a "coal famine" in the land. Nobody can desire a repetition of the coal famine of 1873-5, either in the interest of miner, owner, or consumer. A short period of abnormal prices, although wages followed them, must do incalculable mischief. Take the example of 1873. The high prices of that period stimulated the efforts of coal-owners in all directions. Forsaken pits were reopened, new veins were exploited, mines that did not pay expenses under ordinary conditions were sold to companies or eager speculators; and in this way the number of collieries at work was increased from 2760 in 1871 to 4933 in 1875—an increase

of about 80 per cent. within the four years. Similarly, the number of men and boys employed in and about the coal-pits of the United Kingdom grew in the same four years from 371,000 to 538,000; being an increase of about 45 per cent. The coal production, however, did not correspondingly increase. The output of 1871 was 117,352,000 tons, while that of 1875 was 131,867,000 tons, which is an increase of only about 12 per cent. These figures show the waste of effort under extreme pressure. Every possible endeavour was made at this period to obtain coal, which was selling at famine prices; but the result was a lamentable failure. To obtain an additional output of 12 per cent., the working staff was increased by 45 per cent., and the pits by 80 per cent.; meaning that the extra labour did not earn its cost, and that the capital sunk in the new mines was for the most part thrown away. It is consequently easy to understand that neither capitalists nor labourers have any cause to expect benefit from a repetition of these conditions. The men, perhaps, suffered most from the fitful fever. The high wages demoralized them; and the inrush of fresh hands, which no trade societies could keep out, dragged down the wages afterwards to starvation point. Some of the 167,000 extra men and boys recruited from town and country, and put to coal mining during the "flush times," returned to the places whence they came; some drifted into other industries, and swamped them; others remained to starve in 1883 in the localities where they caroused in 1873. On all sides the coal famine, as it was called, was repeated after a time by other consequential famines more deserving the name.

If the prospect of a break in the deadly monotony of the gas coal trade for the past ten years should have the effect of putting a stop to the abuses that have crept into it, the result would be worth buying at the price of a considerable rise in the cost of the commodity. What Shakespeare calls "the cankers of a calm world and a long peace" have been too conspicuous in this branch of commerce. The middleman and middle influences have developed into rank luxuriance, like baneful weeds sapping the substance of the land on all sides. It is a remarkable fact that all the scandals that have lately arisen in connection with the purchase of coals for gas making have applied to cases where a middleman has been employed. The manager of a well-known colliery, by way of illustrating the influence of middlemen, once declared to us that he often competed for contracts unsuccessfully against agents selling his own coal. The wonder is why such things should be. The coal trade, especially in some districts, is poisoned by middlemen. Take the case of Halifax, which is now figuring conspicuously in men's minds. It is notorious that Mr. Ellis Lever, a coal agent, is at the bottom of the attack that has been made here upon another coal agent, Mr. E. G. Wrigley, and others. Mr. Lever has also stirred up the gas authorities of Salford and Leeds; alleging that some other coal agents are defrauding them. This sort of thing may be all right and proper in the estimation of some people; but does it not look as though anybody who dares to buy coal through any other agent may sooner or later have to endure the doubtful honour of being made a recipient of Mr. Lever's threatening telegrams? The question is, Are these middle people necessary in the scheme of the British gas industry? One can understand that in some trades a middleman can sometimes buy large quantities of stuff from a needy seller, and can afterwards retail it at prices lower than those for which the same article can be obtained in the open market. But coal is not largely stocked; and one is driven to ask why consumers who buy so extensively as do most gas companies, cannot always deal at first hand. Many do, as we know; and these are free from a vast amount of annoyance. The plain fact is that unlimited competition—that great panacea of the hide-bound Free Trader—while it is a good thing in the main, has its "seamy side," like most other human institutions. There are as upright, fair-dealing coal-owners in the land as there are honest and faithful gas managers to deal with them. Unhappily, but naturally, there are sellers who prefer to obtain business by underhand means; and they do not lack accomplices on the other side. Competition is so keen, that if one canvasser for orders begins to use occult influences, others will outbid him. So the unholy game goes on—one outbidding the other, until at last somebody finds it more profitable to start on a different tack altogether. It is at least probable that, if the race of middlemen were wiped out, purchasers would feel easier respecting the appropriation of their money; so that, if prices were raised either for the benefit of the coal-owner or the miner, or of both together, it

would be certain that the additional payment would go to the rightful claimants, and not be swallowed up on the road. There is some talk of a huge Coal Trust, with a capital of £80,000,000 sterling, to be constructed on the lines of the Cheshire Salt Trust. If such an organization should be formed, it would have the not insignificant effect of removing the occupation of the middleman, who lives by setting one coal-owner against another. On this account we may wish the attempt success.

THE MEETING OF THE MIDLAND ASSOCIATION.

The members of the Midland Association of Gas Managers met in Birmingham on Thursday last, under the presidency of Mr. Henry Hack, M. Inst. C.E., under whom the Association has had two prosperous and comfortable years of existence and work. Mr. Hack will now resign his charge to Mr. C. Taylor, of Derby, who will doubtless do his best to preserve the Association from any falling off in efficiency during the coming year. The business of the meeting comprised the adjourned discussion on Mr. J. T. Lewis's paper on "The Competition of Petroleum with Gas for Lighting Purposes" (presented at the previous meeting), and the reading of a paper by the President-Elect upon high heats in carbonizing. We shall, of course, publish the usual report of the proceedings in an early number. The discussion upon Mr. Lewis's paper, although interesting and useful so far as it went, was not particularly instructive—that is to say, very little transpired with regard to the experience of members in connection with the extension of the use of gas among classes of the population who do not ordinarily patronize it. Perhaps it would be correct to say that there was no information available upon the point; Mr. Lewis's own departure in the direction of weekly collections being avowedly an experiment of an unfamiliar kind. So far Mr. Lewis has expressed himself as being well satisfied with the promise of his experiment; and he is a man who can be depended upon to tell the truth from time to time as his experience discloses it, without reference to whether or not it suits his own preconceived ideas. Hence we are justified in regarding the Wellingborough venture as a rather important and decidedly interesting one. During the discussion, a good deal was said respecting the advantages or the reverse of forcing gas consumption upon people who have been accustomed to do without it, and whose custom is, after all, too small to make it very much worth while to run after it. While admitting the force of objections of this order, we venture to remark that any gas manager who means to take in hand the work of popularizing gas among all classes of the community will find himself sadly hampered at the outset if he begins by distinguishing too curiously the consumers whose custom does not pay from the others. The attention of the meeting was engrossed by Mr. Taylor's remarks upon carbonizing temperatures; but, as the subject was reserved to be discussed at the next meeting, there is not much to be said about it now. We will be content with observing, with reference to the single point of stopped ascension-pipes, that ninety-nine gas managers out of a hundred, when they discover that to push their heats beyond a certain limit means trouble with the pipes, will quietly keep on the safe and comfortable side, whatever may be the other inducements to cross it. The President of The Gas Institute was present at the meeting, and was appealed to for a statement respecting what is to be done to terminate the existing crisis in the existence of the body whereof he is the head. He thereupon declared that he would produce a policy immediately after the meeting of the Council next month; which promise soothed his interlocutors. It is an illustration of the far-reaching effects of the deadlock in the Institute that the Midland Association will not go on with their contemplated work of technical instruction while the Institute scheme is in abeyance through the withdrawal of the bulk of the members to whom was entrusted the duty of carrying into effect the resolution passed last June. The meeting ended in a dinner, according to custom.

PETROLEUM EXPLOSIONS.

CONSIDERABLE alarm was spread through Europe last week by the explosion of the petroleum-laden steamer *Ville de Calais* in the harbour from which the ill-fated craft took her name. The newspapers spread far and wide the mysterious intelligence that she was a "tank" steamer, as though the term implied something dreadful; and the minds of the general public of newspaper readers were not reassured by the statement that tank steamers have of late largely superseded the vessels that used to carry oil in barrels. It is a

lamentable characteristic of the ordinary newspaper reader, judging from his behaviour upon such occasions as that now in question, that he never learns anything concerning what is going on round him until his incuriousness is broken in upon by some dire catastrophe; and he then fills the air—or the columns of the newspapers—with frantic appeals to Government, or the Police, or somebody, to “do something” instantly. So he continues screaming incoherently until his attention is taken off by another sensation. The explosion in the harbour of Calais has aroused a little excitement about the safety of the Thames; for it is rightly argued that if so much damage can be done in a small port, what might not happen in London or Liverpool from the vast quantities of petroleum daily received into these great commercial centres of importation and distribution? It seems to be admitted that the explosion of the *Ville de Calais* was due to the careless introduction of a naked light into one of her tanks when empty of oil; for a tank steamer resembles a gasholder in being more liable to explode when temporarily thrown out of use than when full of its ordinary contents. Human carelessness, however, is an ineradicable constituent of the chances of life; and it is not pleasant to reflect that the momentary aberration of an overworked sailor or sea-going engineer might cause a repetition of the Calais disaster in any of our most crowded waterways. It is futile to grumble upon this score, however. Petroleum we shall always have with us, like the poor—for whom, indeed, it is largely required. The only thing to see to is that petroleum tanks, whether afloat or ashore, are managed with all possible care, and, so far as possible, put out of the power of hurting anything, whatever may happen to them. Meanwhile, as Mr. Charles Marvin writes to *The Times* to point out, startling catastrophes like the explosion of the *Ville de Calais*, although they make more noise in the world, in more ways than one, are not chargeable with more than a small percentage of the total damage done by petroleum in the land. The worst offender is the cheap lamp, which kills from 200 to 300 people annually without anybody noticing it. Coal mines, tank steamers, and coal gas explosions altogether do not kill so many people as common lamps, against which there are no laws or regulations, and which do not come under supervision by inspectors.

A QUESTION OF TRIFLES.

The gas managers who took part in the discussion, at the Midland Association meeting, of Mr. J. T. Lewis's paper on the competition of petroleum with gas (mentioned in another paragraph), seem to have overlooked one or two very plain considerations that might well have been referred to on that occasion. First with regard to the question as to which classes of consumers are profitable, which is one of the central points of the doctrine of the advisability of extending the use of gas. The quality of being profitable is not an entity that can be disentangled from all the other circumstances of the connection in which it is sought. There is no standard in this matter, or it is a shifting one. No single consumer of gas in any large undertaking could be regarded as profitable at the price he pays for his gas, if it were not for the others. Hence there is a sense in which it may be said truthfully that no consumer “pays;” and is it too much to claim that there is also a sense in which every consumer pays? Take the example of an insurance company. The rate of fire insurance for an ordinary domestic risk is 1s. 6d. per cent., and any office will gladly accept a single £100 at this rate, going through all the routine of writing out the policy and entering up the business, and collecting the premium at the regular times. Does this “pay?” In one sense, of course not; but in another sense it is all “good business.” We are aware that the analogy is not quite perfect; but a better one may be found in the example of the pushing tradesman who will send the smallest order home to his customer's address, although the direct profit upon it may not pay for the errand boy's time. One cottage consumer of sixpennyworth of gas a week in a street would not pay; but would not a hundred more of such consumers in the same street be worth having? It is rather a deplorable thing for these small consumers that the custom in England is to speak of the price of gas by the unit of 1000 cubic feet. It is too large a unit for common use by small consumers; 100 cubic feet is quite large enough. This is the exact equivalent to the Board of Trade unit for electrical supplies. Thus we can see from this example that, albeit unconsciously, the tendency in favour of a smaller and more manageable unit has been accentuated. Electricity at 8d. per unit does not sound nearly so dear as gas at 6s. 8d.

per 1000 cubic feet. In the countries which have adopted the metric system, the unit for the sale of gas is the cubic metre, or 35·316 cubic feet, which is almost too small for gas, yet it masks the high price of gas in many places, because the value of such a unit can be expressed in centimes—again a small denomination. This is a point that has been mentioned in the *JOURNAL* upon previous occasions, but it will bear repetition in connection with such topics as that discussed by the Midland gas managers last Thursday.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 734.)

THE general tendency of the Stock Exchange markets during the past week has been downward. Some degree of uncertainty as to the course the Money Market would take prevailed; and this had its effect. Apprehension as to the spread of the colliery strikes was also entertained, which had its influence on railways; and a more or less general lack of support all round made everything inclined to be dull. There was more doing, however, in the Gas market than has been the average for two or three weeks past. The changes in quotation are but few; and they are somewhat irregular. Gaslight “A” has not been very active; but the firmness it exhibited the week before has grown more marked, and rather better prices have been easily obtained. The quotation has risen 1. The “H” stock, on the other hand, failed to maintain the advance it had made in the preceding week, and fell back to a similar extent. A little was done in the 10 per cent. preferences at old prices. South Metropolitan have been unusually active—especially in the beginning of the week, when they showed out fairly steady. The “B” weakened towards the end, and fell 3; but the “A” closed unchanged. Commercial have been very quiet; but the old stock has receded 3. There is no sufficient reason, so far as we are aware, for these reductions. The colliery strike has been alleged as one; but we cannot agree in the sufficiency of that. Among the Suburban undertakings, Brentford continues to be the most to the front; and a fair amount of business in the old shares has been done at good figures. Of the Foreign Companies, Imperial Continental has been strong, and marked top price on Friday. The Directors announce that they will recommend their usual 5 per cent. dividend for the half year at the approaching meeting. Bombay old was dealt in once or twice, but nothing was done in the new; though at the Mart on Wednesday some of the £4 paid shares realized 5½. The Para Company, which is coming more prominently into notice since its resumption of the payment of dividends, was also moderately dealt in; and we now include this Company's quotation in our stock and share list. The Water Companies have been pretty active, and for the most part steady. Lambeth marked a further fall during the week, but recovered before the close; and the only relapse is in New River debentures.

The daily operations were: On Monday, Gas issues were very quiet, except South Metropolitan, which showed great activity. The “B” fell 1; though the closing mark was the best of the day. There was nothing noticeable in Water. Tuesday's Gas business was moderate, and more evenly distributed through the list. Gaslight “H” fell 1. Water was hardly noticed, but New River debentures receded 1. On Wednesday, Gaslight “A” and Brentford old were moderately dealt in; but everything else was very quiet. In Water, Lambeth 10 per cents. fell 2½. Thursday's Gas business was only noticeable for the improving tendency in Gaslight “A,” which rose 1. Water stocks ruled fairly firm. Lambeth debentures were 1 higher. Friday was rather a quiet day in Gas; and business was mostly in Gaslight issues. Commercial old fell 3; and South Metropolitan “B,” 2. But nothing was done in either. In Water, Lambeth 10 per cents. recovered their fall of 2½. Both Gas and Water were rather more active on Saturday than usual, and pretty steady. All quotations closed without further variation.

ELECTRIC LIGHTING MEMORANDA.

THE WATERHOUSE SYSTEM OF ELECTRIC LIGHTING—GAS PREFERRED TO ELECTRICITY AT NEW ORLEANS—THE QUESTION OF INTRODUCING ELECTRIC LIGHTING INTO HARROW—MR. J. E. H. GORDON AND THE “ELECTRICAL REVIEW.”

A FEW weeks ago we had to chronicle the offer of a London firm to introduce a new system of electric lighting, bearing the name of Waterhouse, into Leamington, to compete with Messrs. Chamberlain and Hookham. We remarked at the time that the name of Waterhouse was strange to us; and we could not give any information respecting the system of electrical supply so called. Since those remarks were published, however, particulars of the Waterhouse arrangements have reached us from the United States, from which we extract the following general description. It appears that the system made its first appearance in a very small way two years ago; but it is said to have advanced so rapidly in public favour as to be now reckoned among the best in use. No technical description of the apparatus has been published—on account, it is said, of considerations with regard to the patents. Sufficient protection has been obtained, however, to enable the broad lines of the invention to be publicly explained. The centre of the system is a so-called “automatic regulator,” consisting of a

pecially modified dynamo, so wound and proportioned that the generation of electricity is always directly regulated to the requirements of the lamp circuit. "The Waterhouse regulator varies the electro-motive force directly with the resistance on the lamp-line, producing self-regulation, and maintaining on the lamp-line the standard current, whether one lamp or the full number are burning. By this method, as the lamps are cut out, the current is reduced in the dynamo, even to the fraction of an ampere; and so it is apparent that one light on the Waterhouse dynamo can be maintained for any length of time without producing more than the standard current." This is the description given in the *American Gas-light Journal*; and, of course, must be taken for what it is worth, as no data whereby the statement may be checked are available. The Waterhouse arc lamp, which this wonderful self-regulating dynamo supplies, is described as inaugurating a new family of lamps, not at all like anything that has gone before. It is sensibly remarked as curious that, at this time of day, a system of electric lighting free from suspicion of copying or infringement should be evolved; yet this is the high praise accorded to the Waterhouse system. Beyond the general assertion that the Waterhouse plan is economical in operation, nothing is advanced on the commercial aspect of the scheme; and there is no novelty in this claim.

Seeing how strenuously the general superiority and popularity of electric lighting in the United States is insisted on by electricians on this side of the water, a report such as the following comes with all the force of a revelation. At New Orleans a movement is on foot for beautifying the streets by voluntary effort, in furtherance of which an open-air concert was recently arranged. The organizers of the movement, in order to provide against possible disaster, were driven to write to the Secretary of the Gas Company a somewhat extraordinary letter, containing this appeal: "Inasmuch as the present system of lighting [electric] is totally unreliable, and we cannot depend upon having light even when most needed, we take the liberty of calling upon you, as a staunch friend of this community, and a liberal contributor to all occasions of public benefit, to furnish us with gaslight around the square for the above occasion." Comment on this statement would be superfluous.

A meeting of the ratepayers of the Harrow district was recently held, as noticed in our last week's issue, to consider the question of introducing electric lighting into the town. Representatives of at least two electrical firms were present; so the reproach of undue favouritism for any particular system could not lie against the organizers of the meeting. The proceedings were enlivened at times by sharp conflicts of assertion and denial between enthusiastic friends of electric lighting and those who professed scepticism respecting its efficiency and economy as compared with gas. One or two speakers were put up to belaud electricity; one gentleman being bold enough to prophesy that the adoption of electric lighting by the Local Board would lead to a reduction of the rates, the lowering of rents, and a consequent revival of the popularity of the neighbourhood as a place of residence. This, in face of the experience of the next-door suburb of Barnet, was almost too much for the patience of the meeting; for there was no lack of witnesses to the costliness and uncertainty of this system of lighting. Harrow is, after all, only a suburb; and as most of the residents have business connections of some kind with London, it was more than many of the people who attended the meeting could be persuaded that a system of lighting which has been frequently tried and found wanting in the City would be perfectly satisfactory in an outlying district. Still, the meeting adopted a resolution asking the Local Board to "investigate the question whether the electric light can be introduced to the advantage of the town;" and this will do no harm, if care is taken to prevent local partisans from misrepresenting this very innocent resolution as a declaration in favour of the system of lighting in question. The Local Board happened to meet on the following night, and duly received a copy of the resolution of the public meeting, which they promptly referred to the Lighting Committee, one of the members of which remarked that he should want something more definite than anything he heard on that occasion to favourably impress him with regard to the suitability of electric lighting for Harrow.

Things are not very pleasant between Mr. J. E. H. Gordon, the Manager of the Metropolitan Electric Supply Company, who have now commenced business at Whitehall, and the conductors of the *Electrical Review*. The latter have, in fact, offended Mr. Gordon by publishing at various times uncomplimentary notices of the Paddington electric lighting installation, for the design of which he is responsible, and which forms the subject of the amusing extract from the *St. James's Gazette* which appears in another column. When the Metropolitan Electric Company was floated amid the plaudits of the press, the *Electrical Review* was among the few technical journals that refused to listen to the voices of Stock Exchange charmers, who would have claimed their flashy allotment as tantamount to a proved success in working; and they placed the bitter drop in Mr. Gordon's cup of triumph by asking "How about Paddington?" Mr. Gordon loftily declined to say anything about Paddington, or of the circumstances under which the electric lighting department of the Telegraph Construction and Maintenance Company, of which he was the head, was suddenly shut up. Recently the *Electrical Review* got wind of the fact that there had been some hitch in the lighting of the Avenue Theatre, which is served from the Metropolitan Company's very complete Whitehall establishment, and they applied for information as to

the facts. In response, Mr. Gordon allowed his temper to appear through the terms of a letter in which he recommended his interrogators to go to the Avenue Theatre, and see for themselves that the lighting was all right; implying at the same time that this would be a better employment for their time than writing unpleasant things about the Metropolitan Electric Company and himself as the working head. When will people learn that it is the worst of all possible mistakes to show temper when assailed by a newspaper? Mr. Gordon's manifest irritation and injudicious surliness laid him open to a damaging retort from the Editors of the *Electrical Review*, who had nothing to lose and everything to gain by disclosing the correspondence, and this they have accordingly done.

THE VENTILATION OF GAS-LIGHTED BUILDINGS.—In the list of prizes offered by the Société Technique du Gaz en France for competition at the annual congress next year, there is one of 3000 frs. (£120) for the best paper on the ventilation of gas-lighted buildings. In reference to this prize, the Committee have issued a special "programme" indicating the lines on which they think the subject may be best dealt with, but, of course, without birding the competitors in any way to their suggestions. They advise special attention to the practical side of the question; and state that preference will be given to the paper which describes the results of experiments actually carried out.

PRESENTATION TO MR. ALDERMAN H. LEE, OF WAKEFIELD.—On Wednesday, the 17th inst., the Corporation of Wakefield recognized the long and able services rendered by the Mayor (Mr. Alderman Henry Lee) in connection with municipal matters, and more particularly with the carrying out of the new scheme of water supply, by conferring upon him the first honorary freedom of the city. The ceremony took place at a special "evening dress" meeting of the Council; and the presentation was made by Mr. Alderman Mander, J.P. In the course of his remarks, he alluded to the fact that next month Mr. Lee will have completed a 32 years' connection with the Corporation, during which period he had, he said, been either Chairman or Vice-Chairman of numerous Committees, not the least important being the Water Committee, over which he had presided from its constitution until that day. Mr. Lee had been elected twice to the aldermanic bench, and thrice to the dignified office of Mayor. A record like this was not a mean one; but one of which anybody might well be proud, and it ought to serve as an example to all young men. He concluded by expressing the hope that the Mayor might be long spared to perform useful service, and would look back upon his life with the thought that it had not been spent in vain. The scroll bearing the honorary freedom was placed in a silver casket, having upon it a plate with the following inscription:—"Presented, with the Honorary Freedom of the City of Wakefield, to Alderman Henry Lee, J.P., Mayor, as a token of the esteem and regard in which he is held by his fellow-citizens, and in recognition of the faithful discharge by him of public duties during his membership of the Town Council—a period of more than 30 years—and especially for his unceasing exertions in obtaining and carrying out to a successful issue the scheme for a new water supply from Rishworth Moors, 10th October, 1888." Upon another plate are engraved the names of the subscribers. The Mayor expressed his deep obligation to the Council for the honour they had conferred upon him, and the proceedings closed. Subsequently the Mayor was entertained at a banquet in celebration of the event.

FINDING WATER BY DIVINATION.—The *Morning Post* continues to keep its columns open to correspondence on the subject of the divining-rod; and some extremely interesting letters, written from various points of view, have appeared in our contemporary since this matter was last noticed in the editorial portion of the *JOURNAL*. Some of the writers are incredulous; others fantastic in their theories; while a few seem to be upon the right track. One of the sceptical letter-writers suggested that a professed rhabdomantist should be blindfolded, and, rather prematurely, expressed the belief that he would then be unable to use the rod. This theory, however, is disposed of by another correspondent, who alleges that he not only covered the eyes of one of the experts whose names have been mentioned, but resorted to other expedients for the purpose of testing the powers he claimed to possess, and which, notwithstanding the difficulties purposely created, the rhabdomantist proved himself still able to exercise. The writer of a more recent letter to the *Morning Post* has adverted to what Mr. John Stears, of Hull, has written on the subject (see *ante*, p. 602) as probably containing the true key to the phenomena in question. Mr. Stears stated that if he stood upon some china dishes all his power was lost; thus giving rise to the inference that the power he possesses has its origin in electricity. This is the very point to which attention was specially directed in our article on the subject which appeared in the issue of the *JOURNAL* for the 9th inst. In referring to Mr. Stears's theory, we pointed out that the same thing had been experienced by Bleton, the remarkable hydroscope to whom Mr. Baring-Gould makes allusion. It is now stated—but we do not know at the moment whether or not the statement is correct—that this form or action of electric force was long ago discovered by Mr. Cromwell Varley, whose omniscience as an electrician is beyond dispute. Undoubtedly it is true that electric currents from the earth are constantly passing through our bodies, though the further development involved in the manifestations of the "divining" or searching rod are at present beyond our ken.

Notes.

GAS-HEATED ROLLS FOR IRON.

A remarkable application of gas for an industrial purpose is described in a recent issue of *Engineering*. It is stated that before rolling-mills can be started in work at the commencement of the week, the rolls must be gradually and carefully heated. If this is not properly done, the unequal local expansion caused by contact with large masses of red-hot metal will cause fracture of the rolls, and thus entail serious loss. Generally this necessary preliminary heating is effected by lighting coke fires under and round the rolls, or by placing large pieces of hot metal near them, or even by passing through them some thin metal. These devices are at best of a makeshift character, however, and are so uncertain in their action that breakage of the rolls is not a rare accident. To ensure uniform and regular heating of rolls, Mr. Franklin Heaton, of Middlesbrough-on-Tees, has devised a simple but effective gas arrangement. It consists of gas-pipes fixed by temporary connections in a position parallel to the rolls, one on each side. These pipes bear a number of gas-jets, which, when lighted, gently yet thoroughly warm the rolls, which are meanwhile slowly revolved. The two upper pipes are connected with the riders, and rise and fall with the roll. Obvious as the use of gas for this purpose and in this way seems, it appears to be a great novelty. The system effects a considerable saving in rolls, for in one mill the average life of a pair of rolls previous to the application of gas was not quite 80 days; whereas after the adoption of the system it was 342 days. In another large mill, with rolls 36 inches in diameter by 9 feet long, weighing 17 tons each, only two rolls have been broken since the system was adopted, and both cases were due to neglect of the men to turn on the gas. As regards cleanliness and ease of application, the gas process of heating is manifestly greatly superior to the methods it has replaced.

LACQUER FOR IRON AND STEEL.

A new preservative of iron and steel has been found in a modification of the well-known Japanese gum-lacquer. After many experiments, the preparation has been finally adopted for the Imperial Japanese Navy. There is a certain difference between the compound prepared for painting iron and steel and the ordinary lacquer employed for wood; but its principal element is still the gum-lacquer. The inventor of the new composition had great difficulty in conquering the tendency of this material to get very hard and then to crack; but, according to the reports, he has succeeded at last. Experience has shown that a ship protected with this variety of lacquer has been able to keep afloat in tropical seas for three years—going into dry dock only once instead of six times during that time, as usual. A ship of the Russian Pacific Squadron has tried the new coating, and the result has been very satisfactory. It is consequently thought that at last a tolerably perfect anti-corrosive coating for iron and steel structures has been discovered, which may render substantial service in the preservation of all descriptions of erections in these materials. The first cost of the preparation is rather high; but it is claimed that the excess of cost is more than compensated by the protection obtained. For ship use it is also asserted that great advantage accrues from the high polish which this lacquer retains while the coating remains perfect; but, on the other hand, fears are expressed that the supply of gum-lacquer will be unequal to the demand, if the requirements for these engineering purposes are added to the regular consumption of the article for ornamental joinery and cabinet-work.

ACTION OF PRODUCTS OF COMBUSTION UPON STEAM-JETS.

Herr R. von Helmholtz has communicated to *Wiedemann's Annalen* some observations made by himself upon a jet of steam. He remarks that a jet of steam escaping from a hole of 1 or 2 mm. diameter, lighted obliquely and observed upon a black background, is invisible at the lower extremity, and presents towards the top the well-known whitish appearance. This aspect may be modified in many ways. If an electrified point is brought near the steam, the jet immediately becomes azure blue, or, according to the power of the electrical machine, purple, red, yellow, green, &c. These tints are intimately connected with the dimensions of the liquid drops; and hence it follows that the electrical point has the power of provoking condensation of the supersaturated vapour which is found at the lower part of the jet. The same result is obtained by bringing near to the steam-jet a platinum wire made brightly incandescent by an electrical current; or silver, iron, copper, or brass wires simply made red hot in a flame, or even glass heated below the red, or an organic matter, wood, paper, &c., in a state of slow combustion. The products of any flame whatever, with the exception of the flame of pure alcohol, directed upon the jet of steam by the aid of a chimney or by simple blowing, produce a very energetic effect. Finally, traces of certain chemical substances introduced into the steam-jet cause the same modification. Among these are hydrochloric and nitric acid; but concentrated sulphuric acid especially shows the phenomenon. It is known that solid dust particles provoke the condensation of supersaturated vapours; but their presence cannot be invoked here to explain the preceding facts. The author is of opinion that they may be attributed to a molecular concussion, the effect of which may be compared to that of mechanical concussion upon superheated or supersaturated liquids. A flame, for example, is the scene of closely approximated and extremely varied movements; and the chemical atoms which are incessantly passing in it from one

combination to another are found in every kind of unstable condition. These movements and changeful states of equilibrium leave their traces in the products of combustion at a certain distance from the flame properly so called, and determine the observed phenomena. The luminous effect produced at the extremity of an electrified point and the presence of ozone in its vicinity show that this point is the cause of concussions comparable to those provoked by active combustion; and the analogy between the two phenomena is found again in the fact that they both furnish means for making electricity pass through gas. As to solid incandescent bodies, they can act either through the emission of solid particles from their surfaces or by the chemical concussions which they communicate to the surrounding gases.

FLEXIBLE GAS TUBING AND FITTINGS.

The *Revue Industrielle* illustrates and describes a new connection for flexible gas-tubes. It is remarked that the flexible tubes manufactured of continuous spirals of white metal enclosing a thread of india-rubber between the joints are preferable to all others in the market. They are particularly convenient for gas; being without odour, easy to keep clean, durable, and free from liability to break. When used for water, they resist considerable pressure, do not rust in air or water, can be laid along the ground without suffering damage, and withstand severe blows. Up to the present time it has been a drawback to these pipes that there has been no wholly metallic connection for them; but this lack has now been filled by an invention of M. Poujade. This consists of a metallic piece capable of being simply screwed upon the helical spirals of the tube. This fitting terminates at the other end in a hemispherical head, covered with a shield revolving on its axis, and enclosing a bayonet joint. The shield may be turned round sufficiently to admit the end of a gas-cock or other fitting which is to be connected to the flexible tube, and it is then turned back again, pressing the enclosed fitting against an india-rubber ring, which makes a perfectly gas or water tight joint. The appearance of the connector is very neat; and it gives a workmanlike finish to the tube. These metallic flexible tubes are made by the Société Industrielle et Commerciale des Métaux, and the new Poujade connection is sent out with them in all sizes.

THE biography of the late Sir William Siemens, authoritatively prepared, under the direction of his executors, by Dr. William Pole, F.R.S., will be published immediately by Mr. Murray.

THE Directors of the Sheffield Gas Company have presented their *employés* with bonuses of 5 and 10 per cent. respectively on their salaries—the former amount to those who have been in the service less than five years, and the latter to those who have served for more than this period—in recognition of their devoted attention to their duties.

It is reported that Messrs. Armstrong, Mitchell, and Co., of Newcastle, are about to try the economy and efficiency of gas power in their steel works; having given an order for the fixing of a "Stockport" gas-engine in one of their departments. It is understood that, in the event of this engine proving satisfactory, other orders will follow.

THE Society of German Engineers offer a prize of 5000 marks (£250) for the best essay containing a critical estimate of experimental investigations concerning the passage of heat through heated surfaces, in its relation to material, form, and position of the latter, as well as to the kind, temperature, and motion of the heated substances. The essays are to be in the hands of the General Secretary of the Society by Dec. 31, 1890.

Two more deaths are reported from contact with electric lighting wires—this time at the Valladolid electrical station. A carpenter who was doing some work in the place, although he had been told not to touch any apparatus, foolishly took hold with both hands of some high tension wires; and the electrical attendant, seeing that the man could not free himself, went to his rescue, and tried to pull him off. Both men received a shock, and were instantly killed.

THE municipal authorities of Hanover stipulate for certain conditions to be complied with as to the weight and size of lead pipes to be employed on the water-service before any connection is allowed with the town mains. Among other conditions it is provided that a pipe 1 metre in length and 12 millimetres in internal diameter must weigh 4.84 lbs. Similarly a pipe 20 mm. diameter must weigh 6.91 lbs.; 25 mm., 11 lbs.; 30 mm., 15.40 lbs.; and 38 mm., 22.44 lbs.

AMONG the new works announced by Messrs. Crosby Lockwood and Co., we notice the following: "The Mechanical Engineer's Office Book," by Nelson Foley; "The Number and Weight Calculator," showing in single tables the value at 421 different rates (from $\frac{1}{16}$ th of 1d. to 20s.) of any number of articles from 1 to 20,000, or any number of tons, cwt., qrs., and lbs., from 1 to 1000 tons, by Wm. Chadwick; "Plumbing," by W. P. Buchan; and "Modern Workshop Practice," by J. G. Winton.

THE greatest recorded wind pressures during the past quarter on the Forth Bridge were:—7 lbs. on the large gauge at Garvie Castle, on June 11 and July 11; 15 lbs. on the small gauge at Garvie Castle, on July 11; 16 lbs. on the small revolving gauge at Garvie Castle, on July 11; 8 lbs. on the small gauge at North Queensferry platform, on June 11 and July 11; 10 lbs. on the small gauge at South Queensferry platform, on June 11; and 22 lbs. on the small gauge at Garvie platform, on June 11.

THE PARLIAMENTARY REGULATIONS AS TO GAS COMPANIES.

By WILLIAM LIVESEY.

It may be useful to those gas companies who contemplate applying to Parliament in the ensuing session to know that, by an alteration made last session in the Standing Orders, the notices which have to be advertised in the local papers during November are now only required to be inserted twice instead of three times as heretofore, but that there must be an interval of seven days between the two insertions; and the last must not appear later than the 27th of the month. It may also be useful to point out that the recent obligation imposed upon gas companies to raise all new capital by auction, together with the power to regulate dividends by the price (known as the sliding scale), have so disarranged all the old regulations of the Gas-Works Clauses Acts that, unless those Acts are altered, or some provisions made in the Special Acts to counteract the effect of these new regulations, they are likely to prejudice the companies in a manner not expected, and I take upon myself to say not intended.

Under existing regulations, gas companies are required to distribute new capital rateably among the present shareholders; and are allowed to create a reserve fund equal to one-tenth part of the paid-up capital, and to borrow on mortgage or debentures a sum equal to the one-fourth part thereof. If, therefore, a company under these regulations required to raise a further sum of (say) £10,000, they would issue shares to that amount; and then when the shares were paid up, they would be empowered to borrow a sum of £2500 (one-fourth), and to create a reserve fund of £1000 (one-tenth). But if the shares had to be sold by auction, the company would only issue £5000 instead of £10,000, as the premiums would be sure to make up the other £5000; and thus, although the whole of the £10,000 would be invested in the undertaking, the *paid-up capital* would only be £5000, and consequently the borrowing powers would only be £1250, and the reserve fund only £500. It may fairly be assumed that the authorities, in directing that all new shares should be sold by auction, had no intention of reducing the borrowing powers and the reserve fund in this way, and that if provisions are inserted in the Special Acts to obviate this effect, they will be allowed. A general provision in the Special Act to the effect that, in all cases where the powers to borrow or to create a reserve, insurance, or any other fund are limited by the *paid-up capital*, the premiums shall be reckoned as part of that capital, would meet the case.

The reserve fund of 10 per cent. under the Gas-Works Clauses Act, 1847, is chargeable to revenue, and is applicable to the following purposes:—

To answer any deficiency which may at any time happen in the amount of the divisible profits; and

To meet any extraordinary claim or demand which may at any time arise against the company.

Under the sliding scale, this fund is abolished, and instead thereof two other funds are authorized—viz., an insurance fund and a reserve fund, with separate powers to each. The insurance fund is still chargeable to revenue, but is limited to 5 per cent. upon the *paid-up capital*, and is applicable "to meet any extraordinary claim or demand" alone; its object being that if any unforeseen calamity were to happen on the works, requiring great expense to repair, the company should have an insurance fund to meet it, and not have to charge it on the consumer by increasing the price of gas. The reserve fund, being thus relieved of this casualty, is made applicable to supplementing dividends alone; hence it stands on an entirely different footing from that of the insurance fund, and consequently, instead of being made up and maintained by the revenue, as heretofore, it has to be made up and maintained by the shareholders themselves out of moneys they might otherwise appropriate to themselves as dividends, which, under the sliding scale, are practically unlimited. It is, however, optional on the part of the shareholders to have a reserve fund or not as they think fit. They can, if they prefer to do so, pay the dividends in full to which they are entitled as they occur, and leave the future dividends to take care of themselves.

The general provisions by which these two funds—that is, the insurance and the reserve fund—are authorized are to the following effect:—

Insurance Fund.—If the clear profits of the undertaking in any year amount to a larger sum than is sufficient to pay the standard rate of dividend, the excess beyond the sum necessary for that purpose may be invested to form an insurance fund, until the sum amounts to the one-twentieth of the paid-up capital of the company.

Reserve Fund.—Where in any year the dividends on the ordinary share capital or stock of the company shall exceed the standard rate (that is, the old maximum rates), . . . then out of the amount of the divisible profits in excess of such standard rate the company may create a reserve fund, and invest the same in Government or other securities, &c., &c.

There is no apparent necessity for the power to create these funds being clogged with these conditions as to the rates of dividend; and inasmuch as there is no power to create the funds in this form, except under these general provisions, the conditions are

obstructive rather than otherwise, and ought to be expunged, and the power to create the funds made absolute, irrespective of the rates of dividend, whether they are above or below the standard rates. If the profits were only 1 or 2 per cent., and a company considered it better to apply them to an insurance or reserve fund than to divide them, they ought to have the power to do so; but under these general provisions the right to create the funds might be called in question at any time.

The insurance fund being chargeable to revenue, the consumers have an interest in it. It is therefore only right that it should be invested in some readily convertible security. But the reserve fund, being made up by the shareholders themselves, at their own cost and out of their own moneys, the investment of it, or otherwise, ought to be left to their own discretion. If it answered their purpose better to keep it floating as working capital (with or without interest) than to call up new capital for the purpose, they ought to be allowed to do so. If it were all lost, the public would not suffer by it.

The general clause which authorizes the creation of a reserve fund under the sliding scale, provides that any reserve or other fund existing at the time shall be applied to, and form part of the reserve under the sliding scale. This at first seems to be in favour of the companies; but it may fairly be questioned whether it is so or not. Taking into account the object of each fund, it surely would be better for all parties that the insurance fund should be made up first out of any existing fund, and the balance only be applied to the reserve. In truth, it would benefit all parties if it were made compulsory that the insurance fund should be filled up before any extra dividends were paid. If the insurance fund were made up first, the revenue account would at once be relieved of all charges respecting it, and the profits be increased proportionately; and this would be far more remunerative to the company than investing the amount as a reserve at a low rate of interest, considering the very limited application of the reserve fund under the sliding scale. The having a large sum of money invested at a low rate of interest for this purpose does not commend itself as either a wise or an economical proceeding. The difference between a reserve fund under the Act of 1847 and under the sliding scale is not sufficiently taken into account.

There is also another point in which the sliding scale operates inequitably on both shareholders and gas consumers; and that is the dividend. The provisions of the sliding scale are, that for every penny of increase or decrease in the price there shall be, inversely, a decrease or increase of dividend at the rate of 5s. (or one-quarter) per cent., whether the maximum rate is 10 or 7 per cent. If, therefore, the maximum rate were 10 per cent., this increase would be at the rate of 6d. in the pound upon the amount receivable; but if it were at 7 per cent. only, the increase would be at the rate of 8½d. in the pound. Or if the price were reduced 4d., and the increase of dividend made 1 per cent., the difference between the two would be 2s. in one case and 2s. 10½d. in the other; and so in proportion for any larger amount. Or, to put the matter in another form, any well-established gas company can sell shares by auction so as to get all the money required for extensions at 5 per cent. If, therefore, a company required (say) £10,000, and their maximum dividend was 10 per cent., they would sell shares or stock amounting to £5000, and get another £5000 from premiums. But if their maximum dividend was only 7 per cent., the premiums would be less; and consequently the shares or stock would be more. So that, to get the same amount of money at the same rate of interest, the proportions would be £7000 shares or stock and £3000 premiums.

If, then, the company were able to pay an extra dividend of 1 per cent., the result would be as follows:—

£5000 at 11 per cent.	£550
7000 at 8 "	560

At first the new capital bears only a small proportion to the old; but as, when the new capital commences, the old is determined once and for ever, while the new capital increases every year, the latter soon becomes the larger proportion, and the extra charge something considerable. It is, therefore, obvious—paradoxical as it may seem—that it is more economical, both to the companies and the consumers, to issue new capital at 10 than at 7 per cent.

At the time when the sliding scale was under consideration, this difference was objected to by the Gas Companies' Association; but the authorities said: "Our object in making it is that all classes of shareholders shall have the same interest in, and benefit from a reduction in the price." And so it passed; but as it is now obvious that it does not have this effect, but that, on the contrary, it gives a far greater benefit to one class of shareholders than to the other (and to the new shareholders instead of the old), it ought to be discontinued. Either the increases and decreases on the two classes ought to be made specially proportional, or the 7 per cent. capital ought to be reduced to its equivalent in the 10 per cent., so as to make but one class.

Of late years it has been the practice to insert in Gas Acts a provision that, in the event of the profits not being sufficient to pay the maximum dividends on each class of capital, there shall be a proportionate reduction on each class. This, as a matter of course, is only intended to apply to companies under the ordinary maximum dividends; but nevertheless it has frequently been inserted in the Acts of companies under the sliding scale, which expressly provides that the increase or decrease of dividend shall be the same on each class of capital all round, irrespective of any difference in the maximum rates.

WATER BY MEASURE.

By METER.

(Concluded from p. 633.)

What, I ask, is the difference between the present charges for water and a charge by meter? Take a number of houses occupied by the working classes—say, 40 houses, the rateable value of which is £32 per annum. On an average, these houses are using 30 gallons per head per day, without stint or restrictions. This is equivalent to 1s. 6d. per 1000 gallons. This class of consumer will prefer to have water *ad libitum*, rather than be hampered with meters and other responsibilities. They are benefited by having an unlimited supply; and fever and disease are kept from our midst. If I take the same number of houses occupied by the rich, they would gain some advantage by having a meter supply; thus making a law which would benefit the rich, and, on the other hand, lessen the comforts enjoyed by the poor.

It is stated by meter advocates that the revenue has been increased by the adoption of the meter system in certain towns in America; but on inquiry, I find the consumption has been 150 and 170 gallons per head per day, and meters were introduced because it was impossible to sustain the pressure. They made no attempt, however, to stop the waste by systematic night inspection or any of the many methods in vogue in this country. The greatest evil they had to contend with was the unprotected pipes in the houses; and the tenants made it a rule to leave the taps running to prevent freezing. In the towns where the water supply was under the control of the local authority, it would have been a cheaper plan to have fined those leaving the taps running than to have resorted to the expensive and questionable plan of partial measurement. Of course, the adoption of meters would reduce this waste, and besides cause a saving in coal, &c., at the works. We are not told, however, what was the cost of the meters, or the rate charged per 1000 gallons; nor if every tapping was metered, or (as is the practice in many of these metered towns) whether only the water supplied to the large consumers and those found wasting water was measured. In most of the American towns where meters are used, a number of restrictions are taken into consideration—viz., (1) Only large water consumers have a meter—such as extensive flats and tenement houses, restaurants, railways, slaughter-houses, and other business premises. (2) If a man owns a house and pays a tax to a certain amount, he is provided with a meter free; but the man renting apartments upstairs pays for his meter. (3) Meters are used only where the returns are a certain amount per quarter. (4) Meters are not used for small consumers. (5) The authorities make a discrimination in allowing the use of meters, and obtain payment in advance; the minimum rate being £2 per annum to small consumers. (6) Meters are fixed, although a charge by assessment is made; and if the consumer is found to use more water than the amount of the assessment, then they are compelled to pay by measure. (7) Meters if set in dwellings must be furnished, and set at the expense of the city (New York); in all other cases the expense falls on the owner of the premises, and is a lien on the property.

How would a "Water by Measure" Bill of this character work? In numerous instances, the following would be the result:—Take a fashionable seaside resort, where most of the houses are kept by widows and maiden ladies. These people must stint the use of water, and work the meter as they are accustomed to do in the supply of gas. No one will admit that too much scrubbing and cleaning is done at present, although volumes of water are allowed to run to waste in sinks and closets, thus keeping the house comparatively sweet. These people in the first place would stop the few buckets of water required for the scrubbing of passages, steps, and pavements. Then the floors, cleaned all too seldom at present, would be still more neglected; and the rinsing of plates and dishes under an open tap must be stayed, and water used that is already causing an unpleasant odour to rise throughout the house. Again, the present unlimited supply of water to water-closets day and night, when the house is full of visitors, must be checked; and it does not require much foresight to predict what the state of these houses would be if stinted of a copious supply of water. In fashionable boarding houses plenty of water is used during the season. During two-thirds of the year, however, the house is doing little, and it is then when fevers will become prevalent through lack of sufficient cleansing, scouring, and flushing. But the water company must still be diligent in reading, cleaning, repairing, and protecting the machines from frost and injury; and there is no adequate payment for the same amount of trouble and expense incurred when little water is consumed. There is not only the sanitary side of the question to be considered, but the disasters to hot-water apparatus, kitchen boilers, baths, &c., would be very great. One can foresee the frequent visits of the medical man; a very high death-rate; and no advantage accruing to the class of people mentioned. Supposing that a house is closed for some weeks, and the tenants or lodgers return to an empty house, if they pay for the water by meter, all the stale water in the cistern would be used, instead of being drawn off; the dead water in the pipes would also be used, resulting possibly in diphtheria among the younger members of the family. We know of very many cases of this sort occurring every day. How much worse would be the result if all water was metered and paid for? It would be preferable, much easier, and more economical, to cleanse the house, cisterns, and pipes, flush the sinks, traps, and drains, without let or hindrance, than to send for the man to read the meter, and neglect all sanitary precautions necessary on moving into a new house. Running water is necessary in the pipes to preserve the supply pure; but by meter it would be

measured off drop by drop, and never can be as pure as if used through the pipes *ad libitum*.

It is stated that the waste of water is too great to be of service in a public sanitary point of view; the sewage having to be pumped up again. But these assertions are never given with figures that we may judge of their truth. Having had some experience in a town of 25,000 inhabitants, and ascertained that the quantity of water used is 30 gallons per head per day, I find that the authorities have used seven million gallons in flushing the sewers. Now if, as is stated by the meter advocates, the rate per head is to be curtailed to 15 gallons, then it is evident that, unless a far greater amount is used to keep the sewers perfectly flushed, fever must ensue, leaving out of the question the abominable state of a certain class of houses, and considering the amount of water said to be wasted and used, the valuable information so freely disseminated among the people, and the number of sanitary inspectors employed. If 15 gallons of water per head are supplied, or, as may be the case in a number of towns, 25 gallons are used, does it follow that the 10 gallons are absolutely wasted? Looking at it from a public sanitary standpoint, it cannot be useless, but rather a splendid system of flushing or cleansing the sewers, which, if not effected in this manner, must be done by the public authority.

In a paper recently read by Mr. R. F. Grantham, M. Inst. C.E., before the members of the Surveyors' Institution, on "The Water Supply of Villages," it is stated that less than 3 gallons per head per day is an ample supply for cottages,* while most water-works engineers have placed it at 20 gallons and even 30 gallons per head. Regarding the matter from a health point of view, which will be most assuring to the general public? Perhaps these workmen's cottages are contiguous to the semi-detached villas with their garden supplies, &c., consuming 40 gallons per head; but anything is considered by some people good enough for the poor, until disease and death make sad havoc among them. Then it is that plenty of water and great precautions are to be enforced. Whatever quantity of water may be considered as the fair average to be granted per head per day, in most towns, allowing for contingencies and protection from fire, &c., I contend that 30 gallons, and not less, is what we may very well appropriate, and what should be given in a really well-ordered, flourishing, and busy town, having every sanitary improvement, and where the authorities are specially desirous to maintain an exceedingly low death-rate. Ridiculous low rates per head may be quoted, but most of the readers of the JOURNAL must know that to be restricted to 5 gallons per head per day points to an insanitary state of affairs.

In all the arguments advanced for the use of meters, we find no schedule of expenses for inspecting, reading, and general superintendence of these machines. It appears to be taken for granted that the collection of the rates would go on as smoothly as at present, and be collected at the same cost; but experience has shown that the expense is certainly one-fifth in excess of the existing mode of collection, and is productive of endless lawsuits. A water-meter working under pressure is a different thing to a gas-meter. The question resolves itself into whether the works are owned by a company who must pay a dividend on the capital, or by a corporation incompetent to make a profit, and who borrow from other rates to compensate for blunders. The most economical, efficient, and satisfactory plan is that now in use, and which the corporations who have acquired water companies' properties have not sufficient courage to change, although advocated by experts before the transfer.

ON Saturday, the 13th inst., the members of the Liverpool Engineering Society inspected the Vyrnwy Water-Works of the Liverpool Corporation. The party were conducted by Mr. G. F. Deacon, M. Inst. C.E., under whose supervision the works have been carried out; and therefore the chief features of interest in connection with this vast undertaking were fully explained. The centre of attraction was, of course, the great masonry dam, which not long ago gave rise to so much controversy. The party also visited the Hirnant Tunnel, which is 7 feet in diameter and about 2½ miles long, and at its outlet is joined to the aqueduct. This tunnel extends to a building called the straining tower, which, from an engineering point of view, is one of the most interesting portions of the work. The principles of construction and the nature of the machinery to be used were fully explained. The aqueduct conveying the water from the tower to the existing Prescott reservoir is about 68 miles long, and will, when complete, consist mainly of tunnels and three lines of pipes, only one of which, however, is at present being laid down. At the close of the visit, the President of the Society (Mr. C. H. Darbishire) expressed to Mr. Deacon the thanks of the members for his courtesy in affording them an opportunity, on three different occasions, of inspecting the important works they had just visited. He said they all anticipated that success in them was already assured, and felt satisfied that they would for all time prove a lasting monument of the professional ability by means of which they had been created, and of the enterprise, courage, and sacrifices of the great commercial city of Liverpool in providing the necessary ways and means. Mr. Deacon, in the course of his reply, said one of the most pleasing things in connection with the construction of the dam was the fact that the resisting power of the masonry was greater than was in the estimate, and its stability was beyond question.

* See JOURNAL, Vol. LI., p. 286.

Technical Record.

MIDLAND ASSOCIATION OF GAS MANAGERS.

The Thirty-third General Meeting of this Association was held last Thursday, at the Grand Hotel, Birmingham. The President (Mr. Henry Hack, M. Inst. C.E., Engineer of the Saltley Gas-Works of the Birmingham Corporation) presided; and there was a good attendance of members. After the minutes of the previous meeting had been read by the Honorary Secretary (Mr. W. R. Cooper, of Banbury), and confirmed, a discussion arose on the report of the Committee with regard to the scheme for the endowment of technical lectures, which was agreed upon at the last meeting.* It was then decided that the Midland Association should work in conjunction with The Gas Institute for the furtherance of the scheme of technical education sanctioned by the larger organization. In consequence, however, of recent events, the immediate result of which has been to put a stop to further progress in this direction, the Committee of the Midland Association recommended that the Association should support a local scheme of lectures, to be delivered by one of the Professors of Mason's College, Birmingham. But this proposition was met by an amendment directing the postponement of action until it should be seen what The Gas Institute propose to do in the matter; and, after some discussion, it was resolved to defer taking any steps for another year. The adjourned discussion on Mr. J. T. Lewis's paper on "The Competition of Petroleum with Gas for Lighting Purposes," presented at the Bath meeting (see JOURNAL for May 22 last, p. 913) was then opened, and some interesting statements were made by various speakers on the subject, which will be fully reported in a subsequent issue. The discussion concluded with a cordial vote of thanks to the author for the painstaking way in which he had prepared his facts. Mr. C. Taylor, of Derby, then read a paper entitled "An Oft-repeated Question: Are High-Carbonizing Temperatures Convenient and Profitable?" The communication, which is given in another column, was well received; but, owing to shortness of time, the discussion was postponed till the next meeting. The formal business of electing officers for the ensuing year was next proceeded with. Mr. C. Taylor was unanimously elected President in succession to Mr. Hack, and returned thanks for the honour conferred upon him. The resignation by Mr. W. R. Cooper of the office of Honorary Secretary necessitated the appointment of a successor; and Mr. J. S. Reeves, of Bilston, was selected. Messrs. W. R. Cooper, W. Littlewood, and J. F. Bell were elected in place of the retiring members of the Committee. This concluded the general business of the meeting; and the members afterwards dined together.

THE COMMERCIAL VALUE OF SPENT PURIFYING MATERIAL.

In the notice of the papers read at the Boulogne congress of the Société Technique du Gaz en France which appeared in the JOURNAL for July 24 last (p. 162), brief reference was made to a communication by M. Chevalet, dealing with the question of the commercial value of spent purifying material, and indicating how this could be improved. The text of the paper has since been published in a French contemporary, from which the following full translation has been prepared:—

For some time there has been a demand for the spent materials employed in gas purification; and it has seemed to me to be of interest to inquire why certain of these materials have been accepted and others refused by buyers. According to the information I have been able to procure, these products are specially sought for on account of their richness in nitrogen; and before making a purchase, it is usual to ascertain the total quantity of this property, in whatever form, the stuff contains. The composition of spent purifying material is very variable, and very complex, as will be seen from the following analysis by Vivien de St. Quentin:—

	Per Cent.
Moisture	21.50
Mineral substances	33.00
Nitrogen—	
Volatile or ammoniacal	2.12
Soluble of the sulpho-cyanides	2.64
Insoluble or cyanic	1.12
Organic and volatile matters	39.62
	100.00

This analysis does not make any mention of the sulphur which always exists in these products, and in greater quantity in proportion to their age. M. Mallet states that he has obtained products which were found to contain from 40 to 50 per cent. of sulphur.

Spent purifying material is sometimes in demand for the extraction of the ammonia or of the sulpho-cyanides therefrom, or for burning out the contained sulphur. According to the requirements of the buyers, the stuff must possess different qualities. It is generally bought according to the total proportion of nitrogen in it; and it has been ascertained that good products yield from 8 to 9 per cent. Some, however, have been found to contain more; and these naturally fetch higher prices. Very often they contain only 3 per cent. of nitrogen; and in some cases only 0.80 per cent. has been found. Nitrogen fetches, in these materials, from 60 c. to 1 fr. per unit, according to its richness and to the position of the gas-works. It is therefore advisable to fix in the stuff the greatest practicable

quantity of nitrogen; for by so doing it will be possible to recover and even to make a profit on the purchasing price of the original material. In support of this statement, I will cite the Brussels Municipal Gas-Works, from which during last year there were sold 14,741 frs. worth of products, with an outlay of only 2932 frs. in the purchase of the original material. As in these works about 70,000 tons of coal per annum are converted into gas, the gross produce was 21c. per ton.

What must we do, then, to obtain spent purifying material rich in nitrogen? The question as thus put is a little complicated, for it depends largely upon the material originally employed. I am not in possession of any definite data on this point; but I can nevertheless give a few indications—

1. Before the gas reaches the purifying material, it should have been completely freed from tar, if it is desired that this material should last long, and be capable of absorbing a large quantity of nitrogen and sulphur.
2. Heavy and useless material, such as coke dust, tan waste, lime in excessive quantities, and oxides of iron having but feeble purifying power, should not be put into it to separate it.
3. The material should not be washed before being sold; for if this is done the ammoniacal nitrogen and the sulpho-cyanides are dissolved, and nothing is delivered to the purchaser but a damp mass, of value only for its cyanates and sulphur.
4. The stuff should be dried before being despatched. To this end it should be allowed to acquire heat in small heaps, in order that it may not take fire; and it must not be watered, as when intended for use again.

Of all the materials employed in gas purification, those which seem to absorb nitrogen most readily are those which are prepared with sulphate of iron and lime, or Laming's material, because they are capable of containing at the same time both ammonia in the state of sulphate, and cyanates, and sulpho-cyanides; while Lux's material, or those prepared with iron turnings, or natural oxides cannot assimilate ammonia at all, or only very slightly. The best base for the purifying material is unquestionably coarse deal sawdust. Buyers do not like tan waste, because it gives them a good deal of refuse in the sifting, and especially because it has a bad appearance; the purifying material being always black or green on account of the tannates of iron, which, with the salts of iron, always form tannates that are black or greenish. The worst material for selling again is decidedly that which is made with natural oxides. The products are heavy; and they do not absorb much nitrogen, nor last long.

In view of the greater desire now displayed in the industries to turn to account waste or unutilized material, it is of importance for gas manufacturers to look out for a purifying material that is capable of absorbing a large quantity of nitrogen in the form of cyanates and sulpho-cyanides, and even of sulphur. The result will be that such material, being rich, will bear the cost of transport, and of being dealt with in works for this purpose. The gas engineer who devotes his attention to this special detail of manufacture will find at the end of his financial year that purification, instead of being an expense, will be a source of profit, which will go to swell that which he obtains from the ammoniacal liquor produced when he thoroughly washes his gas.

THE STANDARD METRE.—The Committee charged with the supervision of the International Office of Weights and Measures, established at St. Cloud, have commenced their annual session, under the presidency of General Hanez, the Director of the Spanish Geographical and Statistical Institute. One of the problems which more especially concern the Committee is the verification of the metre. The present standard metre at St. Cloud is made of platinum and iridium. This is now to be verified; and it is proposed that the definite selection of a standard metre shall take place next year, when representatives of the twenty-two nations which have adopted the metric system will assemble in Paris. It is proposed to keep, in addition to the standard metres, two copies of it at St. Cloud, and to supply one copy to each nation, accompanied by a description of its manufacture, and a statement of possible error in length as compared with the original standard metre.

MR. ELLIS LEVER AND THE SALFORD GAS UNDERTAKING.—Mr. Ellis Lever having declined to meet the Sub-Committee nominated by the Salford Town Council, at their meeting on the 3rd inst. (see *ante*, p. 645), for the purpose of hearing from him certain revelations in regard to the conduct of the gas undertaking, has written to the Manchester papers in justification of his decision. He states that when he offered to give information to a Special Sub-Committee of the Council, he considered very carefully the conditions on which the offer should be made; and he had excellent reasons for putting the matter in the form he did. The non-acceptance of his condition as to the nomination of some members of the Sub-Committee by himself, he regards as an obstacle placed in his way by the Council for a specific purpose. He says he is still prepared to carry out the undertaking given in his published letter of Sept. 26; but his condition as to the nomination of the Committee must be observed. He deprecates the construction of his refusal as an indication that all the members of the Sub-Committee are obnoxious to him; but the fact of their all being either ordinary or *ex officio* members of the Gas Committee renders absurd, in his opinion, their appointment for the purpose he has in view.

* See JOURNAL, Vol. LI., p. 423.

SOUTH-WESTERN (U.S.A.) GAS ASSOCIATION.

The First Annual Meeting of this newly-formed Association was held at Galveston, Texas, on Aug. 20 last. The President (Mr. F. Beck, Superintendent of the Galveston Gas Company) delivered an Inaugural Address. In the course thereof he said that the first gas plant in the south-west section of the United States was erected at Galveston in 1859; and since then a gradual advance had taken place, so that at the present time there were in Texas alone 20 or more gas-works in successful operation, the largest having a maximum daily consumption of nearly 150,000 cubic feet. Attempts to introduce both oil and water gas had been made, but with no great degree of success. In 1879 the Brush Company commenced the supply of electric arc lights at Galveston, and later on added incandescent lights. Whilst confident that gas companies could compete favourably with, and earn better profits than, electric light companies, he held the opinion that it was best that the supply of electricity should be in the hands of the gas companies. Both gas and electricity, he said, were demanded by the public; and in their small towns a division of business between two lighting companies would render it difficult for either to secure fair returns on the capital invested. Having the advance of water gas, oil gas, and electricity to consider, the necessity for such an Association as they were commencing that day was evident. They worked with nearly the same kind of coal, and other circumstances were similar; so it would be greatly to the advantage of all concerned to discuss and compare together the various manufacturing results obtained. They would thus be able to get uniform statistics, and to reach the bottom figure in cost of manufacture and distribution. He expressed himself in favour of offering concessions for day consumption, and touched upon other practical questions. In concluding, he urged that commercial success could only be obtained by their controlling the supply of heat, light, and power; which meant that they must be prepared to supply at low rates what the public desired. It should therefore be the object of the Association to examine all processes without bias. A paper on "Gas Coals in the Texas Market" was read by Mr. Enfield; and this was followed by one on the "Computation of the Cost of Gas to Consumers and in Holder," written by Mr. Brockenborough, and read by the Secretary (Mr. T. D. Miller). Both papers were fully discussed. It was decided that the next meeting should be held at Austin, Texas, on the third Tuesday in March next.

AN OFT-REPEATED QUESTION: ARE HIGH CARBONIZING TEMPERATURES CONVENIENT AND PROFITABLE?

By CHARLES TAYLOR, of Derby.

[A Paper read before the Midland Association of Gas Managers last Thursday.]

Mr. President,—My time and attention have been so largely occupied lately with other necessary work, that I could gladly have avoided adopting your suggestion to provide a paper for the attention of members at this meeting. I, however, felt it my duty to obey your call if possible; and in casting about for a subject, I adopted, as most ready to hand, a question which, in one form or another, has been very frequently repeated—viz., that at the head of my paper. There are, I believe, many gas managers who still incline to the opinion that the disadvantages arising from the employment of high heats outweigh the advantages; and this fact provides me with an excuse for again presenting the question.

The disadvantages to which the advocates of low heats refer are enumerated somewhat as follows:—

1. Stoppages in ascension-pipes and hydraulic mains, &c., due to deposits of pitch.
2. Stoppages in manufacturing plant and in distributing mains and services, due to deposits of naphthalene.
3. Reduced quantity and quality of tar.
4. Reduced quantity of ammonia.
5. Reduced illuminating power.
6. Increased quantity of sulphur compounds.
7. Increased consumption of fuel.
8. Increased wear and tear of retort-settings, &c.

We probably agree that, subject to qualifications, these charges, or some of them, are correctly made out; and I propose to estimate, as closely as I can, the degree in which they prejudicially affect the cost of production, when the make of gas is raised, for example, from 9000 to 10,000 cubic feet per 20 cwt. of coal carbonized.

I may premise that the tendency to stoppages by pitch and naphthalene has been met, minimized, and modified in various ways—as by the rotative use of different qualities of coal, by reducing the seal of dip-pipes, by the separation of tar from the gas immediately upon their arrival at the hydraulic main, by water-jacketing, steaming, and the occasional lowering of temperature, &c. But these expedients are not always successful; and when they are found to be so, some cost and labour are involved in their application.

I estimate the disadvantages as follows:—

1. The element of stopped pipes, due to pitch, varies with the special circumstances of each works; but, so far as my experience and inquiries have extended, I am unable to put down the loss under this head at more than $\frac{1}{4}$ d. per 20 cwt. of coal, when carbonized at a temperature to yield 10,000 cubic feet.

2. A similar sum—viz., $\frac{1}{4}$ d. per 20 cwt. of coal—cannot, I think, be exceeded for cleaning out stoppages due to naphthalene, both inside and outside the manufactory.

3. I have found experimentally that an increase of 1000 cubic feet between about 9000 and 10,000 feet has decreased the production of tar by one-third to two-thirds of a gallon, while its specific gravity has increased .02 to .025. The money loss due to diminished quantity and increased specific gravity will vary as the demand for certain products or distillates preponderates; but, assuming the value of the tar at 1d. or 1½d., we may adopt 1d. as the loss per 20 cwt. of coal carbonized.

4. It is, I think, well recognized that low temperatures give low yields of ammonia; and Mr. Lewis T. Wright has shown that the maximum of this product is realized when coals are distilled to produce about 10,000 cubic feet of gas per ton. I calculate the additional ammonia due to an increase of 1000 feet of gas at about 7 per cent.; and its value at 0.75d. to 1.5d. per ton of coal.

5. On reducing a series of records by the same authority, I find that an increase of 1000 cubic feet of gas upon a production of 9484 cubic feet obtained from Derbyshire coals, gives a reduction in illuminating power of not exceeding one-fifth of a candle; and I value this at 2d. per ton of coal.

6. The increase of sulphur in the unpurified gas is found to be about 7.5 grains per 100 cubic feet when the production is increased by 1000 cubic feet. This works out to 28 per cent., which at a mean cost for purifying of 5.15d. per ton of coals (as stated in Field's "Analysis") gives 1.44d. per ton as the cost of purifying from the extra sulphur.

7. To my mind, it does not follow that the increased temperature necessary to give an extra yield of 1000 cubic feet must require a *pro ratâ* increase in the quantity of fuel; but as I do not wish to leave any consideration undervalued, the *pro ratâ* increase in the value may be taken at from 1d. to 2d. per ton.

8. If the extra heat implies also a *pro ratâ* increase in the cost of settings, &c., which I am not prepared to admit, we may put this also at 2d. per ton.

I estimate the cost of manufacturing and delivering 1000 cubic feet of coal gas into the holder, exclusive of interest on buildings, &c., as follows:—

1. When producing 9000 cubic feet of 18.3-candle gas=32,940 candle-units per 20 cwt. of coal—

	s. d.	s. d.
To 20 cwt. of coal delivered into works.	9 0.0	
„ Wages and salaries, carbonizing.	3 6.0	
„ Coke for fuel.	1 7.0	
„ Purifying.	0 6.0	
„ Wear and tear.	2 2.0	
		16 9

By residuals—

Coke.	2 2.6
Tar.	1 2.4
Ammonia.	0 10.7
Sundries.	0 2.3
	4 6

Net cost. 12 3

And 12s. 3d. ÷ 9000 = 1s. 4.33d. per 1000 cubic feet.

2. When producing 10,000 cubic feet of 18.1-candle gas=36,200 candle-units per 20 cwt. of coal—

	s. d.	s. d.
To 20 cwt. of coal delivered into works.	9 0.0	
„ Wages and salaries, carbonizing.	3 6.0	
„ Fuel (see item No. 7).	1 9.0	
„ Purifying (see item No. 6).	0 7.5	
„ Wear and tear (see item No. 8).	2 4.0	
„ Clearing pitch and naphthalene (see items Nos. 1 and 2).	0 1.5	
		17 4

By residuals—

Coke.	2 2.6
Tar.	1 1.4
Ammonia.	0 11.7
Sundries.	0 2.3
	4 6

Net cost. 12 10

And 12s. 10d. ÷ 10,000 = 1s. 3.4d. per 1000 cubic feet.

Hence, 32,940 : 36,200 :: 12.25s. : 13.46s.; and 13s. 5½d.—12s. 10d. = 7½d. profit per 20 cwt. of coal carbonized. This 7½d. upon a consumption of (say) 50,000 tons of coal per annum produces a sum of £1562.

DISCOVERY OF AN OIL SPRING IN CHESHIRE.—At Anderton, near Northwich, in the salt district, the Rural Sanitary Inspector has, it is stated, found a well of petroleum oil of great richness.

A TEST FOR SACCHARINE.—In a recent number of the *Chemical News*, Mr. D. Lindo described the following test for saccharine:—After placing the saccharine with concentrated nitric acid in a small porcelain dish, evaporate to dryness on the water-bath, or by moving the flame of a spirit-lamp to and fro under the dish; blowing on the surface occasionally to facilitate evaporation, and taking care that the heat does not rise too high. If the dish is not allowed to cool, and a few drops of strong solution of potash in 50 per cent. alcohol are added to the residue, a faint yellow colour only will be developed. Spread the liquor over the surface of the dish; and before it has settled to the bottom apply heat with the lamp, as above, quickly all over the under surface of the dish. If the vapour of alcohol happens to ignite, it must be at once extinguished. A great variety of colours will be developed in this way. As the dish cools and moisture is absorbed, the colours fade. By heating they can be reproduced, though not in the same perfection as at first.

THE RUSTING OF IRON.

In the JOURNAL for Aug. 28 last (p. 374), we noticed briefly a paper read by Professor A. Crum-Brown, at the meeting of the Iron and Steel Institute held in Edinburgh in the previous week, in which he described the chemical processes involved in the rusting of iron. The following is the full text of the paper:—

My attention was first called to the subject of the rusting of iron by observing what happens when a drop of rain falls on a clean bright surface of this metal. At first, for a short time, the drop remains clear, and the bright surface of the iron is seen through it; but soon a greenish precipitate forms in the drop, and this rapidly becomes reddish brown. The brown precipitate does not adhere to the iron, but is suspended in the water, and becomes a loosely adherent coating only when the water has evaporated. I may premise that, in speaking of rusting, I mean the formation of rust on the surface of metallic iron exposed to ordinary atmospheric conditions. I do not intend to treat of the corrosion of iron by substances such as sulphuric or sulphurous acid, hydrochloric acid, or any occasional impurities which may be present in the air. It has been conclusively shown that the necessary conditions for the production of rust are: (1) metallic iron, (2) liquid water, (3) oxygen, and (4) carbonic acid—both the latter being dissolved in the liquid water. Iron remains quite free from rust in an atmosphere containing oxygen, carbonic acid, and water vapour, so long as the water vapour does not condense as liquid water on the surface of the iron.

Let us now consider the action on iron of the three substances, liquid water, oxygen, carbonic acid, singly, and then two and two. Liquid water, quite free from dissolved gases, does not act on iron at ordinary temperatures. At high temperatures (very rapidly at a red heat) iron is oxidized by water or water vapour, and is converted into the magnetic oxide of iron. This magnetic oxide is formed on the surface of the iron as an adherent coating; and only when it is detached can the water gain access to lower layers of the iron. Oxygen gas alone does not act at ordinary temperatures on iron. At high temperatures it also converts the iron into the magnetic oxide, which forms an adherent coating. The same is the case with carbonic acid gas acting alone. At ordinary temperatures it is without action. At high temperatures the carbonic acid is reduced to carbonic oxide, and the iron is oxidized to magnetic oxide, which forms an adherent coating. Liquid water with oxygen dissolved in it does not act at ordinary temperatures on iron. This is shown by the fact that ordinary water, exposed to the air, does not rust iron if the water contains a substance such as lime or caustic alkali, capable of combining with carbonic acid and itself without action on iron. As long as the lime or the caustic alkali is there, no rusting occurs. When the lime or caustic alkali has been converted by the carbonic acid of the air into carbonate, then, and not till then, can the carbonic acid of the air dissolve as such in the water; and then, and not till then, does rusting begin. Water, containing carbonic acid dissolved in it, acts on iron at ordinary temperatures, forming ferrous carbonate, which dissolves in the carbonic acid water; forming, no doubt, ferrous bicarbonate. In this way artificial chalybeate water has been prepared by shaking up finely-divided iron with carbonic acid water. In this action, hydrogen gas is given off. Solutions have been thus prepared containing nearly 0.1 per cent. of iron. If oxygen is presently dissolved in the water, it will unite with the nascent hydrogen; and if we have sufficient water, iron, and carbonic acid, the whole of the dissolved oxygen will be thus consumed. The presence of dissolved oxygen quickens the solution of the iron; the tendency of the oxygen to combine with the nascent hydrogen supplying an additional motive to the action. Probably, in ordinary rusting, no hydrogen actually becomes free, as, under ordinary conditions, there will always be enough dissolved oxygen to convert all the nascent hydrogen into water. When a solution of ferrous bicarbonate is exposed to an atmosphere containing neither free oxygen nor carbonic acid, it loses carbonic acid, and insoluble ferrous carbonate is precipitated. If free oxygen is present in the atmosphere to which it is exposed, the ferrous carbonate is oxidized to ferric hydrate; carbonic acid being given off. This, if the water is not already saturated with carbonic acid, dissolves in the water.

We can now follow the whole process of rusting, and divide it into stages—these stages being really separable, if we take proper precautions, but in the usual case overlapping one another. We have, first, the formation of soluble ferrous bicarbonate; secondly, the conversion of ferrous bicarbonate into ferric hydrate, the white ferrous carbonate passing through green and black intermediate substances into the reddish-brown ferric hydrate—i.e., rust. We have to note that the carbonic acid that is dissolved in the liquid water, which is necessary for the process of rusting, is not used up in the process. It is given off during the oxidation of the ferrous bicarbonate to ferric hydrate, and is thus ready to act on the new surface of the metallic iron. The continuation of the process of rusting is not, therefore, dependent on new carbonic acid absorbed from the air, but the original carbonic acid, if not removed, can carry on the process indefinitely, as long as liquid water is present, and oxygen is supplied from the air. When the process is started, it goes on more rapidly, because the porous rust not only does not protect the iron, but favours, by its hygroscopic character, the condensation of water vapour from the air as liquid water. A piece of iron, therefore, which has begun to rust, will continue rusting in an atmosphere not saturated with water vapour—an atmosphere in which a piece

of clean iron will not rust, because liquid water will condense from such an atmosphere on the hygroscopic rust, but not on the bright iron.

NEW YORK WATER SUPPLY.—It is stated to be possible that the great Quaker Bridge dam for the New York water supply may not be constructed for another 20 years, as Mr. Eugene M. M'Lean, of the Controller's staff, has lately sent in a report to the Aqueduct Board, in which he states that though the dam will ultimately have to be built to impound the whole yield of the Croton watershed, estimated at 400 million gallons per day, he thought it would not be required for 25 or 30 years, and ought to be left to the next generation to construct. The cost of the Quaker Bridge dam and reservoir he estimates at £3,190,000; whilst reservoirs capable of serving the city for 30 years to come could be constructed in the upper watershed for £1,032,000.

THE MADRID GAS COMPANY AND THE SUPPLY OF ELECTRICITY.—Writing on the 15th inst., the Madrid correspondent of *Industries* says: The price of gas in Madrid is 9s. per 1000 feet; but the consumption does not even reach 1000 feet per inhabitant per year. The consequence is that the 500 fr. shares of the Company were quoted a few days ago at 380 frs.; and it was expected that there would soon be a further fall, as the electric light has been compulsorily adopted in the theatres, and is also making progress in clubs, restaurants, &c. Notwithstanding this the shares of the Company have suddenly gone up to 448.50 frs. The only way for accounting for this is that, although it has not yet been made public, the Company's claim to have the sole right to establish mains for all lighting purposes is likely to be admitted by the Municipality. Should this be the case, the Company would supply electric light at a rate equivalent to gas at 9s. per 1000 feet.

AN ELECTRIC GAS LIGHTER AND EXTINGUISHER.—An invention by which the turning on and shutting off of gas flowing to a burner is effected by the heating action of an electrical current, and in which the gas is ignited by an incandescent wire, has been patented by Mr. L. Hogan, of Lebanon, Kentucky, although, according to *Iron*, the novelty of the arrangement is doubtful. In combination with a gas-burner is a casing which has a collar fitting on the supply-pipe; two cylinders filled with mercury being mounted in the casing. The lower ends of the cylinder are of reduced size, and are provided with pistons having downwardly extending rods. One of these piston rods rests on the free end of a U-shaped spring, to which is attached a valve-rod passing to a valve in the supply-pipe; the free end of the spring, when pressed down sufficiently to open the valve, being caught by one arm of a right-angled spring catch lever, on the other arm of which rests the piston-rod of the second cylinder. Three conductors are required to operate the burner. To turn on the gas, the current is sent through the right-hand mercury cylinder, by means of an electrically insulated conductor surrounded by heat-conducting material, whereby the expansion of the mercury will press the piston down, and open the valve in the supply-pipe; the end of the spring which presses on the valve-rod being then caught and held by the catch lever. A looped platinum wire is supported in the circuit near the tip of the burner, and is sufficiently heated by the current to ignite the gas. To extinguish the gas, the current is sent by the left-hand wire through the other mercury cylinder; the expansion of the mercury pressing down its piston, and releasing the catch lever by which the valve in the supply-pipe is held open—the circuit being completed by the middle conducting wire rather than by the circuit of greater resistance through the platinum coil.

A NEW OIL-LIGHT FOR OUTDOOR USE.—A drawback experienced with certain forms of outdoor petroleum lights for use on railway sidings and in goods yards and similar situations is that, the combustion being imperfect, a quantity of the vaporized petroleum escapes into the air. This not only means waste, but in some cases damage to surrounding property by the distribution of the oil spray. In order to overcome this defect a new form of industrial lamp, known as the "Jupiter" light, has been devised. It consists of a double chamber, the upper portion of which contains the oil, while the lower one receives the compressed air which passes upwards through a central tube into the oil chamber. Over the latter is placed a metallic double cover of conical form, through the top of which the illuminating flame passes into the atmosphere. The oil chamber is connected by a pipe with a reservoir of crude petroleum, and the air chamber is similarly placed in connection with a receiver in which air is compressed at a pressure of about 20 lbs. per square inch. In starting the lamp, a small quantity of spirit is poured on the surface of the heavy oil contained in the oil chamber; the spirit is then lighted, the covers placed over the flames, and the compressed air turned on. Passing through the centre of the flame and over the surface of the oil, the air causes a high temperature to be rapidly reached and maintained, and an induced current to be produced. The internal conical cover soon becomes highly heated, and thus conduces to the perfect combustion of the oil, so that no smoke is produced nor does any vaporized oil escape into the atmosphere; the inlets for the supply of oil and compressed air being carefully proportioned to ensure this result. The action of the induced current is to raise the gas of the heated oil and at the same time to draw in the necessary supply of air for perfect combustion. A trial of the light took place last Tuesday night on some waste ground on the Thames Embankment; the appliances shown ranging from 100 to 3000 candle power.

Register of Patents.

GAS-LAMPS.—Thomas, T. C. J., of Hornsey. No. 11,305; Aug. 18, 1887. [8d.]

This invention has reference to regenerative or recuperative lamps, or apparatus constructed with inverted burners, and so arranged that air for supporting combustion has its temperature raised on its way to the flame by contact with surfaces heated by the escaping hot gases and products of combustion. An early type of this lamp was described in the specification of Clark's patent, No. 3015 of 1863, which was modified by the present inventor's patent of 1885, No. 883.

Fig. 1 of the accompanying illustrations is a vertical section, illustrating an air-heating chamber combined with a burner of Argand type made according to this (1887) invention. Fig. 2 illustrates a modified form of Argand burner. Fig. 3 shows in vertical section still another modified construction.

In fig. 1, the air-heating chamber comprises a series of concentric nozzles, pipes, or annular divisions in the form of inverted truncated cones combined with an Argand burner composed of a ring of tubes. A is a perforated plate or partition, with downwardly projecting ribs or flanges. B is a nipple or casting provided with a flange or collar to screw into the plate or partition A. By means of it, the air-heating chamber and attached burner are secured to the gas-supply pipe and to an air-supply chamber in the manner described in a former specification (No. 579 of 1887). There is a box screwed into the flange or collar of B, and formed with a tubular part or pocket C, for the collection of dust and dirt separated from the gas supplied to the burner and scale from the gas-pipe. It also serves to carry the tubes constituting the burner. To facilitate the separation of the dust and solid matters from the gas, and thereby prevent choking of the burner, the under side of B is formed with a downwardly projecting flange or tube D, that causes gas flowing to the burner to first pass downward into the pocket C, and afterwards to rise before entering the tubes. With this form of burner, air is admitted both to the centre and to the exterior of the gas-flames. E is a guard surrounding the lower ends of the pipes; and serving to prevent air passing to the central space within the burner at the lower part. F is a nozzle-like guide or deflector, to direct the issuing gas to a focus. The air admitted to the inner space of the air-heating chamber passes between the tubes to the central space, and issuing thence tends to give an outward direction to the flame; whilst the air admitted to the outer spaces is caused on issuing to impinge upon the gas in an angular and downward direction, so that there is a tendency to focus it.

In fig. 2, the burner is in the form of an annular gas chamber of the ordinary kind, perforated at the bottom, and connected to a gas box or chamber by pipes as shown. Each nozzle, pipe, or division (instead of being formed as part of a single truncated cone) may be further bent inwards at its lower end, so as to form part of another cone.

In fig. 3 the conical nozzles, pipes, or annular divisions are each formed with or carried by a perforated ring-like flange or extension provided with an upwardly extending flange. The nozzles are secured in position below the perforated plate A by a tube formed with a flange to support the lowest flange (which is not perforated), and arranged to screw into a rib or flange on the plate A. This construction admits of the nozzles being readily secured together and taken apart when desired. The pocket C in this arrangement is cast in one piece with the plate A. The guard E is secured within the ring of tubes; and a guide or deflector is provided to direct gas issuing from the burner in an outward direction.

GAS-LAMPS.—Thomas, T. C. J., of Hornsey. No. 11,306; Aug. 18, 1887. [8d.]

This invention has reference to lamps (applicable also for heating); the construction or arrangement of burner being such as will produce a divided or duplex flame, to be used either inverted or otherwise, with air for supporting combustion having in some arrangements its temperature raised on its way to the flame by contact with surfaces deriving heat from the escaping hot products of combustion.

Fig. 1 shows in vertical section an inverted gas-burner, suitable (according to this invention) for use in the closed combustion chamber of an ordinary regenerative or recuperative lamp; and fig. 2 is a vertical section of the burner when arranged for use with a chimney or globe open at the top.

In fig. 1, A is an inner air chamber; B, a gas chamber; and C, an outer air chamber. These chambers are mainly formed by three concentric castings or metal casing of approximately hemispherical form, secured at their ends or bases to a perforated plate D. E is a gas-box, with socket for attachment to a gas supply pipe. It is connected to the plate D by tubes which place the interior of the box in communication with the gas chamber B. The inner casings are each formed

with a slot or opening F, and the outer one with a slot G. The spaces between the casings at the two ends of the slots or openings are closed, in order to prevent air passing between the two at these parts. H is a plate or partition dividing the inner air space, and projecting through the slots or openings F G; and provided at each side with an outwardly curved guide or deflector I. The arrangement is such that the gas issues from the gas chamber B towards each side of the plate or partition H in a stream having the contour of an arc of a circle or approximately so.

If the burner shown be secured to the gas and air supply pipes of a suitable regenerative gas-lamp so that the air descends through the inner and outer air chambers A and C in the direction of the arrows shown by full lines, and the gas in the direction of the arrows shown by dotted lines, two flames of peculiar form will be produced; each being curved outward and upward, and having a curved or arc-like cross section. The form of the flame will, however, depend to some extent upon the arrangement of the lamp and of the exit apertures for the hot gases and products of combustion.

In fig. 2, the plate D, gas-box E, and plate or partition H, shown in fig. 1, are dispensed with; and the burner is connected by tubes to the socket D, which is arranged to be secured to the upper end of a gas supply pipe, so that the gas issues upwardly from the burner. The casings are slotted as before; and the intermediate one is provided with a series of holes for the passage of air to the outer air chamber C, and with another series of holes for the passage of air to the interior of a chimney or globe which is open at the top, and supported on a flange or gallery at the lower end of the casing. With this arrangement, two approximately flat semicircular topped flames will be obtained, with an air current at the outer side of each, and with an air current between them.

GAS-LAMPS AND BURNERS.—Quaglio, J. von, and Westphal, C., of Berlin. No. 14,837; Oct. 31, 1887. [8d.]

This invention relates to gas-lamps or burners having a downwardly directed flame with central chimney; and it consists principally "in an improved form of gas-jet applicable to such lamps or burners, and generally in the arrangement and combination of parts of the lamp."

A is the cylindrical casing of the lamp forming the air chamber, and narrowed below to the shape of a hollow inverted truncated cone. In the lower portion of the casing is placed the burner, consisting of the outer inverted truncated conical wall B connected to the outer cylinder at intervals by stays, and projecting inwardly at its upper edge so as to make a flange, which forms a secure joint with the second part of the burner—viz., the inverted truncated hollow conical part C—of greater steepness than the part B, and extending downward so that its lower edge is level with the lower edge of the latter, and at a short distance therefrom in order to form with it an annular jet for the issue of the gas. The gas-pipe may either pass laterally as on the left of the illustration, or vertically downward as shown on the right side, into the upper portion of the space enclosed between the parts B and C. Down the centre of the cylindrical chamber A extends the chimney D, preferably made in one part with a flange, the rim of which is fastened inside the upper edge of the cylinder A, whereby the chimney is supported, and a cover is formed to the cylinder by the flange. The latter may or may not be

perforated for the admission of air into the cylinder. The chimney extending down to near the upper edge of the burner body terminates in, and is continued downward by the tube E, which is made of refractory or heat-withstanding material. This tube extends downward to a suitable distance below the lower rim of the burner, and is then flanged outward to form a flame distributor. There is a flange on the lower edge of the cylindrical portion of the casing A, and a recess is left in the under edge thereof to receive a ring of asbestos material. The rim of the globe G is held firmly against this ring by springs or hooks.

The air entering into the chamber A passes downward on each side of the annular burner, and issues to the flame F; the latter passing outward and downward into the chimney and flue H. To equalize the pressure of gas in a burner of this kind, flanges or plates may be so placed therein as to divide the annular body into two separate portions with passages connecting them. The gas is thus more or less restrained in its passage from the annular space in which it first arrives from the pipe into that from which it issues to the flame.

GAS HEATING-STOVES.—Jackson, W., of Aberdeen. No. 15,167; Nov. 7, 1887. [8d.]

According to this invention, the chamber constituting the casing of the stove is fitted with a burner, the gas for which is supplied through an atmospheric arrangement. The interior of the chamber is fitted with a number of inclined tubes or passages opening at each end to the outside of the chamber, but having no communication with the interior of it. These pipes (by which the air is heated) are preferably arranged in tiers one above the other, and are placed at such an angle that the air of the apartment enters them at one end, becomes heated in them, and passes out from them at the other end; so that circulation of the air of the department through the stove is secured.

GAS-ENGINES.—Davy, C., of Sheffield. No. 15,658; Nov. 15, 1887. [8d.]

This invention has for its object to diminish the consumption of gas or vapour in gas and other engines, by maintaining a higher temperature in the jacket surrounding the working cylinder and combustion chamber—and consequently in the walls of the cylinder and chamber—than is possible when water is used as the cooling agent in the jacket; and avoiding at the same time the danger of overheating which might ensue were no cooling jacket employed. The highest temperature practically maintainable in the jacket, says the patentee, is necessarily lower than the boiling point of the liquid employed therein; and hence it follows that if water be so employed, an excessive amount of heat is abstracted from the working cylinder and combustion chamber, which entails a correspondingly wasteful consumption of gas. His invention therefore consists in a mode of maintaining a much higher (mean) temperature in the jacket—and consequently in the walls of the working cylinder and combustion chamber—by the employment, as the cooling agent, of a fixed oil such as olive oil, the boiling point of which is much higher than that of water at atmospheric pressure.

In carrying out the invention, it is desirable to provide against the oxidation of the oil which would occur, and the objectionable odour which would be given off, if the hot oil were exposed to the atmosphere; and to this end it is necessary that the hot oil should circulate in a closed (or practically closed) system in such a manner that the oil will be sufficiently cooled to prevent the temperature in the jacket rising beyond the desired limit—i.e., beyond the boiling point of the oil, or beyond such a temperature that the piston and rings would become overheated, whichever temperature is the lowest; the circulating system being provided with means of accommodating the variable expansion of the oil without exposing the hot oil to the air.

ALTERING AND ADJUSTING THE OUTLET LIQUID LEVEL IN TANKS OR OTHER VESSELS.—Cutler, S., of Millwall. No. 16,221; Nov. 25, 1887. [8d.]

This invention has for its object the construction of apparatus whereby the outlet liquid level in tanks or other vessels may be altered and adjusted with precision; being especially adapted for application to vessels used in dissolving solid matters.

Fig. 1 is a side sectional elevation of the tank and the partition used when liquids and solids have to be divided (but which partition is not necessary when liquids of different specific gravities are to be dealt with); and fig. 2 is a transverse sectional elevation of the same tank in which no partition is shown.

When necessary a partition A is placed across the tank or vessel B used so as to divide it into two chambers C and D; each communicating with the other at the upper part by reason of the partition not reaching quite to the top. There is also a communication from one to the other near the bottom, by one or more holes E, so that the liquid portion of the mixture may flow into the smaller or outlet chamber D, while the solid matter is retained in C. At a convenient height in the side of the smaller or outlet chamber D is inserted a pipe F, with a specially formed elbow G capable of being partially revolved. To one end of this elbow there is fitted the pipe F, for conveying the out-flowing liquor to its appropriate receptacle. To the other end of the elbow is fixed a radiating hollow arm I. Attached to the elbow there is also a worm-wheel J, which is actuated by a worm K fixed to a spindle L that passes

through the tank, and through the arm of a bracket M fastened to the top thereof; the part of the spindle projecting above the arm being furnished with a handle N, or hand-wheel.

On turning the handle N, the spindle L and worm K will revolve and impart motion to the worm-wheel J, which, being fixed to the elbow G, will cause the radiating hollow arm I to assume any desired angle to the vertical; and consequently its top will be raised or depressed to the requisite level. The liquid contents of the tank may be drawn off to a level corresponding with the height of the top of the hollow arm I, which may be altered or adjusted at pleasure.

THE ARRANGEMENT OF GAS WASHERS OR SCRUBBERS WHEN MORE THAN ONE ARE EMPLOYED.—Cutler, S., of Millwall. No. 16,222; Nov. 25, 1887. [6d.]

This invention—which has for its object the convenience in use, and economy of construction, together with reduced area of ground required for gas washers or scrubbers where a number are employed for the same or similar operation—consists in making one very large vessel, and dividing it by partitions into as many compartments or chambers as are required to effect proper purification. The exterior form of the vessel may be (in plan) a long parallelogram, in which case the house for containing the necessary distributing apparatus extends from end to end of the top of the vessel; or it may be a shorter parallelogram with a central partition subdivided so as to form the requisite number of chambers. Another arrangement may be made by having a vessel of the form of a parallelogram divided by a certain number of partitions, with offsets arranged so as to serve as additional chambers; or the chambers may be made of a hexagonal or octagonal shape, but so grouped together as to admit of one or more sides of one chamber serving as the side or sides of other chambers. By these means it is claimed that great economy in construction is effected, while the area on which the washers stand is much reduced, and the convenience for arranging the appliances for distributing the liquid with which they are supplied is greatly increased.

MIXTURE AND TREATMENT OF MATERIALS FOR ENRICHING COAL GAS AND IN REMOVING OR PREVENTING STOPPAGES IN ASCENSION-PIPES.—Bennett, W. H.; communicated from J. Lamy, of Paris. No. 17,558; Dec. 21, 1887. [6d.]

This invention has for its object the manufacture of a compound for the enrichment of coal gas, and for the prevention and removal of stoppages in ascension-pipes.

The patentee proposes to take any variety of shale or lignite, or brown coal, or cannel, together with shale oil, or any other suitable oil, and grind them together under very heavy pressure, so as to pulverize and intimately amalgamate together the shale and oil. A shale, brown coal, lignite, or cannel is preferred that is capable of yielding the largest quantity of gas; and the oil preferred is that which contains the greatest amount of paraffin or paraffin scale. A good oil to use is one having a specific gravity of .930 to .950; a flashing point of 120°; and a setting point of 65° Fahr. But others may be employed—such as those known as intermediate oil, gas oil, still bottoms, blue oil, green oil, or any waste mineral oil, or oleaginous matters; and in some cases it may be preferred to grind and amalgamate together with the shale and oil a proportion of bituminous coals, so as to improve and strengthen the quality of the coke left after distillation in the retorts.

The proportion in which the oil and shale are mixed depends on the use for which the composition is employed. If for enriching coal gas, about 30 to 40 gallons of oil per ton of shale are used; but if for preventing or removing the stoppages in ascension-pipes, about 50 to 60 gallons to the ton of shale are more suitable.

When the compound is used for enriching coal gas, the quantity of the mixture to be added to the ordinary coal with which the retorts are charged must be proportionate to the quality of the gas it is desired to make; and the effect is that the rich gases eliminated from the compound unite with the poor gas from the coal so intimately that no undue condensation ensues. If, however, it is used for preventing or removing stoppages in the ascension-pipes, a hole is made through the carbonaceous substance in the pipes; and the retorts are then charged with the compound alone, and without any admixture of common coal. The result is that the rich gases given off soften, melt, and liquify the carbonaceous matter, so that it falls down the pipe into the mouthpiece and may thus be easily removed.

PROPOSED ELECTRIC LIGHTING OF LEEDS.—The Leeds Corporation have recently received a number of applications from electric lighting agents and syndicates, with a view to the installation of the electric light in certain districts of the borough; and it is expected that the whole subject will shortly be brought before the Town Council. In the meantime the Electric Lighting Committee have instructed the Borough Engineer (Mr. T. Hewson, M. Inst. C.E.) to prepare a scheme for lighting a sectional area of Leeds, and supplying the light to all shopkeepers and others who may require it.

HELPS'S PATENT PIPE EXTRACTOR.

SIR,—As my Directors had adopted this simple but valuable invention, I read with dismay Mr. E. H. Thorman's letter in your last issue.

Upon inquiry, I find that the clip which was made "about 33 years ago" was practically of the same character as that which I, with others, had also tried and proved useless. The apparatus was fitted with *two* screws to force the pipes apart; whereas the Helps arrangement is designed for, and produces a totally different effect with, one screw. The pipes are (as we have proved here) quickly extracted by their own weight and jarring, when lifted against the point of the screw which takes up the slack after each lifting of the pipe.

I think, therefore, that Mr. Thorman must have misunderstood your description of Mr. Helps's new arrangement.

Richmond, Oct 19, 1888.

THOS. MAY.

THE EDINBURGH AND LEITH GAS-WORKS PURCHASE.

SIR,—Will you allow me to correct a very strange mistake in your Edinburgh Correspondent's "Notes" of last week?

His statements are to the effect that I was entirely opposed to the purchase of the gas-works by the Town Council. This to me is unaccountable. I thought every citizen of Edinburgh was aware that, so far from being opposed, I proposed the purchase of these works by the Town Council in 1863. My plans were then fully considered; and I hold a letter of thanks for them from the then Town Clerk. In 1865, I again addressed a letter to the Council, advocating the purchase and removal, on the grounds of their ineligible situation, incapacity of expansion, and insanitary tendency. At that time, the project was deemed revolutionary; but who does not see now that, had it been then adopted, the citizens would not only have bought cheaper, but have been in possession of a lucrative property instead of one which—at its enormous cost—must for ever afterwards be a heavy burden on the community. I was, therefore, one of the foremost pioneers of the purchase; and the recent schemers were merely appropriators and appliers of the ideas I had then, and have ever since pursued.

But there was certainly a difference between us. My aim was, primarily, the benefit of the community; and I accordingly advised a purchase on fair terms. They, as they avow, had two objects—the benefit of the community, and the Gas Companies too; and they advised a purchase on what I considered most unfair terms. They proposed to give, and have given, the Companies about three times the value of their works, so far as the city's requirements go. That is what I object to; and as I have, in various communications in your columns, expressed my objections in detail, I need not here repeat them.

I must, of course, presume that they have escaped the notice of your correspondent. He cannot, however, but know that, subsequent to the publication of my opinion that it would have been better and vastly cheaper to construct new works in present circumstances, than to buy old and exhausted ones, there was a wide expression of opinion (professional and unprofessional) to the same effect. He also knows that I affirmed that £300,000 would supply an entirely new plant in an eligible situation; and I have no hesitation in adding that, if the tinkering method he applauds be preferred to this, a mistake as great and serious for the community as the deferring of the purchase from 1865 until now will be committed.

Edinburgh, Oct. 19, 1888.

JOHN ROMANS.

CONONLEY WATER COMPANY, LIMITED.—This Company has lately been registered with a capital of £2000 in shares of £1 each, to supply water to the inhabitants of the township of Cononley, in Yorkshire.

THE ASSESSMENT OF THE FALMOUTH GAS-WORKS.—The appeal of the Falmouth Gas Company against the assessment of their works, which some time ago was referred, by consent, to Mr. Morgan Howard, the County Court Judge, has resulted in the reduction of the amount from £550 to £332 8s. 6d., the question of costs to be settled by the parties.

THE ARBITRATION BETWEEN THE WAKEFIELD CORPORATION AND THE RURAL SANITARY AUTHORITY.—Last Saturday the Solicitors to the Wakefield Union Rural Sanitary Authority received the award of Mr. E. Cousins, C.E., of Westminster, the Arbitrator in the dispute which took place some time ago with reference to certain water-mains belonging to the Corporation in the district of the Authority, and which the latter proposed to acquire. The Corporation claimed £53,000 for the pipes, fittings, and other apparatus, &c., and the Authority offered £1038. The Arbitrator awards the Corporation £1544, and directs that his costs, amounting to £311, shall be paid them and the Authority jointly. He does not make any order as to the costs of the arbitration and reference, which, it is said, are very heavy.

THE PUBLIC LIGHTING OF BIRKENSHAW.—At the meeting of the Birkenshaw Local Board last Thursday, the Gas Committee reported that they had taken steps with the view of obtaining particulars as to methods of lighting the district otherwise than by gas, and several letters and proposals were laid before the meeting. Among them was a communication from the Stringfellow Patent Lighting Company, London, offering to light the public lamps at £1 10s. each for the winter, each lamp being estimated at burn 1000 hours. At this stage Mr. W. Oddy was introduced to the meeting. He said that while his sympathies were with the ratepayers, he thought the Board should light the public lamps. He had waited on the Gomersal Gas Company, and they represented to him in the course of the interview that their last dividend was only at the rate of 4½ per cent., but at the present rate of consumption the next would be only 2½ per cent.; and between the consumers on the one hand and the shareholders on the other, the Directors felt very much inclined to give up altogether. He suggested that the Board should enter a protest against the price asked by the Company for the public lighting; but still light up for the winter, and in the meantime give consideration to any other projects for lighting the lamps that might be brought before them, so as to be able to entertain another scheme if necessary next winter. If this were done, there would be no risk to life and limb through the streets being unlighted during this season. Mr. Oddy having withdrawn, the members generally expressed the opinion that, in view of the feeling evinced by the ratepayers, they could not take the course suggested by him. Ultimately it was decided to obtain a lamp from the Stringfellow Company, and have it fixed in a prominent place in the district for trial.

Legal Intelligence.

WEST RIDING QUARTER SESSIONS.

TUESDAY, OCT. 16.

(Before Mr. BASIL T. WOODD, Chairman, and a Bench of Magistrates.)

THE AFFAIRS OF THE RASTRICK GAS COMPANY.

Our readers will remember that at the Spring Sessions (see JOURNAL for April 17 last), an application was made to the Court, on the petition of certain ratepayers of Rastrick, for the appointment of an accountant to investigate the affairs of the Rastrick Gas Company, with the view to an order being made for a reduction in the price of gas. A similar petition had been presented at the previous sessions, but had failed on a technical objection. As the result of the second application, Mr. J. W. Close, of Leeds, was chosen to carry out the investigation; and he now submitted a report setting forth the results of his labours, which extended over 115 days, and embraced an examination of the accounts of the Company since its formation in 1864. The report was as follows:—

I have examined and ascertained the actual state and condition of the concerns of the Company, and find that on the 11th of July, 1864, a Company, called the Rastrick Gas Company, Limited, was registered and incorporated under the Companies Act, 1862, with Memorandum and Articles of Association, and that by the Rastrick Gas Act, 1865, such Company was dissolved, its Articles of Association made void, and its assets and liabilities transferred thereby to a new Company, called the Rastrick Gas Company, to which by such Act enlarged powers were given. The capital of the Company was fixed by the Act at £25,000; and power was given to the Company, by section 20 of such Act, to borrow on mortgage a sum equal to one-half of the paid-up capital when £10,000 had been subscribed for and issued, further powers of borrowing being given in certain proportions as further capital was subscribed for and paid up.

The paid-up capital of the Company, at its commencement in 1865, was £4845; and in 1877 it had been increased to the sum of £14,000.

Section 31 of the Gas-Works Clauses Act, 1847, requires that surplus profits, after providing for the maximum dividend of 10 per cent., shall from time to time be invested in "Government or other securities," and that the dividend and interest arising from such securities shall be similarly invested, in order that the same may accumulate at compound interest until the fund is equal to one-tenth of the nominal capital of the Company, when it is to form a reserve fund to answer any deficiency which might at any time happen in the amount of divisible profits, or to meet any extraordinary claim or demand which might at any time arise against the Company; and the following section provides that no sum of money shall be taken from such fund for the purpose of meeting any extraordinary claim without the certificate of two Justices in that behalf being first obtained. In the year 1877 the reserve fund amounted to £1177 9s. 9d., of which the sum of £500 was invested in Government securities, and the sum of £500 with the Brighouse Local Board; and the Company, having occasion for further money for new works, sold out the Government securities, and borrowed a sum of £670 from the reserve fund, notwithstanding the prohibition contained in the 32nd section of the Act of Parliament above mentioned, and in the following year the further sum of £511 5s. was also borrowed from the same fund. Both these sums have since been paid back to the fund; the last payment being made in February, 1887, and such fund now stands at the sum of £1800, of which the sum of £1289 13s. 8d. is stated to be invested on deposit with the London and Yorkshire Bank, Limited, and £510 6s. 4d. with the Clifton Water Supply Company. In ascertaining the amount of the reserve fund, interest is debited against the Company thereon from time to time, and the fund has not, therefore, suffered in amount by the irregularity referred to; but the course adopted appears to me highly reprehensible, and the investment on deposit with the bankers is, in my opinion, irregular, and not one contemplated by the section of the Act of Parliament prescribing the mode of investment of the reserve fund to which I have already alluded. The nominal capital of the Company is £25,000; and by section 31 of the Gas-Works Clauses Act, 1847, the Company is entitled to create a reserve fund of 10 per cent. on that amount. The amount at which the fund now stands is £1800, which is £700 short of the maximum sum.

The Company seems to have been a prosperous one, for within two years of its existence it paid a dividend of 6 per cent., which went on increasing until 10 per cent. was reached in the year 1872; and for the last twelve years the maximum dividend of 10 per cent. has been paid. So soon as the dividends began to reach the maximum amount, the Company commenced to write large sums for depreciation off the capital item for gas-fittings (which mainly comprise gas-meters), although no authority is to be found in any Act of Parliament for such a course, and notwithstanding that the form of account provided by the Gas-Works Clauses Act of 1871 makes no provision for depreciation except for works on leasehold lands, but, on the contrary, permits to be charged items for the repairing, renewing, and refixing of meters to the revenue account. In this way the Company depreciated in six years an item of £562 2s. by the sum of £542 1s. 10d.; leaving £20 only as the capital value of what six years before was £562 2s., and notwithstanding that in the meantime the revenue accounts had been debited with items for repairs, &c.

The investigation of the Company's accounts has occasioned more trouble than need have arisen, the same having been indifferently kept prior to 1881. Since then, however, the accounts have been intelligible, and much more easily investigated.

In the year 1885 the Company made a larger profit than at any other period of its existence, and found itself possessed of a sum which, with the balance brought forward from the preceding years, would have allowed of a dividend of 17½ per cent. being declared; but, instead of applying this sum towards making up deficiency of dividend in previous years, or adding it to the reserve fund, as provided by section 31 of the Act of 1847, the Company proceeded to write off £1000 for depreciation of plant, and made the profit of that year appear so much less, although there is no authority for such a course, and notwithstanding the early expenditure charged in the revenue account for maintenance of the plant. I find, also, that various sums have been charged to revenue account, which unquestionably should be charged to capital account, and these sums amount to £957 1s. 11d.; but, on the other hand, sums amounting to £279 16s. 3d. have been charged to capital, instead of revenue—leaving a sum of £677 5s. 8d., which the Company is entitled to divide as profit in excess of the amount shown by its accounts. In addition to the items mentioned, there is also a sum of £50 improperly retained by the Company as a fund for bad debts, which is divisible profit; and there is also improperly charged in the revenue account items for income-tax amounting to £621 13s. 4d., which ought to have been deducted from shareholders' dividends, and will therefore need taking into account in reduction of the deficiency of maximum dividend in previous years.

Put shortly, the result of my investigation shows that at the end of 1886 the Company was possessed of divisible profit in excess of the amount

shown by the accounts to the extent of £2269 7s. 6d., made up as follows:—

Depreciation on gas-fittings	£542	1	10
Depreciation of plant	1000	0	0
Items of capital charged to revenue	677	5	8
Fund for bad debts	50	0	0
	£2269	7	6

At this time there was needed to make up the deficiency in maximum dividend for previous years the sum of £2095 14s., less the sum of £629 13s. 4d. applicable in reduction thereof paid by the Company on account of the shareholders by way of income-tax; leaving the sum of £1466 0s. 8d. payable on this account, and to this there needs adding the sum of £700, required to make the reserve fund equal to 10 per cent. of the nominal capital of the Company.

The matter, therefore, stands thus at the end of 1886—

Amount of divisible profit in excess of that shown by the Company	£2269	7	6
Deduct amount required to make up maximum dividend and reserve fund	2166	0	8
Balance	£103	6	10

At the commencement of the year 1887, the Company had, therefore, a sum in hand of £103 6s. 10d., and in that year a profit of £1655 2s. 11d. was made; making a total of £1758 9s. 9d. divisible, which is insufficient to pay the maximum dividend of 10 per cent. on £18,000 (the paid-up capital).

It has been suggested to me, on behalf of the petitioners, that deductions should be made on account of the sums paid for Directors' fees and Manager's bonus, which during the existence of the Company have reached the sum of £1293. But, having regard to the form of account provided by the Act of 1871, in which such items are expressly mentioned, I think that the items are properly entered; but whether the amount is fair or not, I am not in a position to say, nor do I think that the sum of £223 4s. 4d., made up of items under the head of repairs, but which, in reality, consist of wines and cigars for the Directors' use, should be disallowed, as suggested by the petitioners.

By section 35 of the Gas-Works Clauses Act, 1847, under which the Court derives its powers to inquire into the state and condition of the Company's concerns, it is provided that, in case the whole of the reserve fund has been and then remains invested, and in case dividends to the amount limited have been paid, the Court may make such a rateable reduction in the rate for gas as in the judgment of the Court will, when reduced, ensure to the Company a profit as near as may be to the prescribed rate, which, in the case of the Rastrick Company, is 10 per cent. on the paid-up capital. In the Hanley gas case, reported in the Law Reports (19 Q. B. Div., p. 481), where neither the whole of the reserve fund had been invested nor the prescribed amount of dividends had been paid, it was decided that there was no power to order a reduction; and the same state of things exists in the present instance. But apart from this it seems to me that it would be undesirable to order a reduction, having regard to the fact that in 1887 the Company did not make a profit equal to 10 per cent. on its paid-up capital, even if the Court came to the conclusion, notwithstanding the Hanley case, that it had power to make such an order.

I beg, in conclusion, to state that the Company and its officers have afforded me all the assistance I have desired of them; and I have no complaint to make of any document having been withheld.

Mr. KERSHAW and Mr. C. M. ATKINSON appeared for the petitioners; Mr. HEATON CADMAN represented Mr. Close; Mr. E. TINDAL ATKINSON, Q.C., and Mr. BAIRSTOW watched the proceedings for the Company.

Mr. KERSHAW alleged that there had been many improper things done by the Company, which had been a very prosperous one, and had paid 10 per cent. dividend for the past 12 years. Some time ago, the Company finding themselves in a very prosperous condition, resorted to the practice of putting down to revenue what ought to have been charged to capital. These sums came to £957; but, on the other hand, sums amounting to £279 had been charged to capital instead of to revenue, leaving a balance of £678, which the Company were entitled to divide as profit in excess of the amount shown by the accounts. It was also alleged that the Company had accumulated a reserve fund of £2500, and not £1800 as stated by Mr. Close in his report.

Mr. E. T. ATKINSON, on behalf of the Company, contended that the carrying of the investigation over a period of 24 years was contrary to the Act of Parliament under which the inquiry was authorized. What the Court had to deal with was merely the profit made in 1887. His clients had no desire whatever to limit the inquiry; but he must insist that neither the petitioners nor the Court had any authority to investigate the accounts of preceding years, except in regard to their bearing upon those for the past year.

The CHAIRMAN remarked that, as he understood, the Court had to be assured as to the amount of profit made in 1887.

Mr. Close having given evidence as to the correctness of the figures contained in his report,

The CHAIRMAN asked him whether he was satisfied that the clear profit for the year 1887 was £1655.

Witness replied that he was.

The CHAIRMAN said that under these circumstances the Court could not order any reduction to be made in the price of gas.

It was subsequently decided that the Company were to pay the Accountant's expenses; the other costs to follow the event.

LORD MAYOR'S COURT.—WEDNESDAY, OCT. 17.

(Before the Recorder, Sir T. CHAMBERS, Q.C., and a Special Jury.)
WELLMAN v. INCANDESCENT LIGHT COMPANY.—A QUESTION OF COMMISSION. This action was brought by the plaintiff to recover a sum of £27 11s. 3d., which he claimed to be due to him for introducing the defendants' lights to Willis's Rooms, St. James's. The Company contended that no contract had been entered into, and that no money was due.

Mr. W. WRIGHT and Mr. M'CULLAUGH appeared for the plaintiff; Mr. A. COCK and Mr. CHAPMAN for the defendants.

Mr. WRIGHT, in opening the case, said the plaintiff was a gas-fitter, carrying on business in Great Russell Street, Bloomsbury; and the action was brought to recover a sum of money which he maintained he had earned by way of commission. In 1886 or 1887 Willis's Rooms were being attended to by the plaintiff, so far as the lighting arrangements were concerned. About this time he was spoken to by the Chairman of Willis's Company as to some alterations being made in the lighting of the place, as the existing arrangements were considered to be bad. Plaintiff had seen the incandescent light at the Hotel Continental and the Hotel Métropole, and he unhesitatingly recommended the light to Willis's Company. He went to the defendant Company's offices; and he saw a person who was represented to be the Assistant-Manager.

Mr. Cock disputed the authority of Mr. Hulme, whom plaintiff saw.

Mr. WRIGHT said he could prove that Mr. Hulme was the Assistant Manager at a salary of £300 a year. Plaintiff told him that he had an opportunity of introducing the incandescent light to Willis's Rooms; and asked what commission would be allowed. He thought that about 150 lights would be required. Mr. Hulme promised that he should be put on "trade terms," and said the list of these terms was not then printed, but would be ready shortly, and undertook to send him a copy. This he afterwards did. Plaintiff acted under the direction of Captain Clarke, the Chairman of Willis's Rooms; and the Incandescent Company obtained the business and put up the lights, which he believed had been very successful. Mr. Hulme expressed his gratification, as the Company had only just been started (this was in March, 1887, and the Company was only registered on Feb. 14), and they were anxious to get known. He (the learned Counsel) was confident that if they had been able to get hold of Mr. Hulme, the matter would have been settled long ago. By the "trade terms" their commission would be 25 per cent. The defendant Company had put up lamps to the amount of £110 5s.; and 25 per cent. on this would come to £27 11s. 3d. Plaintiff applied several times for his money; and on one occasion had a reply saying that he would certainly receive some "consideration" for his services; that Mr. Hulme had disappeared; and that they had been hoping he might "turn up" again, which was the cause of delay. In reply to another letter, the defendants stated that the matter should be settled as soon as they received the amount of their account from Willis's Company. They had actually received the money from the Company, but had not settled the account.

Mr. Wellman was then examined, and generally corroborated the learned Counsel's statement. On being questioned as to his interview with Mr. Hulme,

Mr. Cock interposed, and stated that Hulme was appointed at a salary of £300 per annum from March 20. His appointment as Assistant-Manager dated from April 26. He had since absconded.

Examination resumed: Witness's men assisted in putting up the lights at Willis's Rooms; and the work he did was equal to about three weeks for one man. He called on Mr. Carey, the Secretary of the Incandescent Company, in July; and at that interview he claimed that the arrangement made with Mr. Hulme should be carried out, and Mr. Carey promised that this should be done.

In cross-examination, witness admitted that he had only received instructions to report on the electric lighting of the rooms, though he had had a large number of questions put to him at various times by Captain Clarke. The lighting of the rooms by electricity was altogether wrong; it was always failing. All orders for incandescent lights for the rooms went through witness's hands, though he had never paid for any.

Mr. Cock said that all the lights were delivered direct to Willis's Company, and were paid for by them. [The learned Counsel here read the circular specifying the "trade terms."]

A JURYMAN asked whether Willis's Company were allowed the discount.

Mr. Cock: Yes.

The JURYMAN: Then why? They are not in the trade.

Cross-examination continued: The time his men were occupied in preparing the chandeliers for the incandescent lights was to be paid for by the discount he obtained on the lights, and was not work done under his contract with Willis's Company. He had been at some trouble in promoting the light.

Re-examined: Captain Clarke asked him to go and make arrangements as to the incandescent lights.

Mr. Cock submitted that there was no evidence to go to the jury.

The RECORDER agreed that there was no question for the jury. How could the plaintiff ask for the benefit of 25 per cent. discount? Discount is a sum of money granted in reduction of a bill incurred by a customer for goods. Here was plaintiff suing for discount like a customer.

Mr. WRIGHT said that with due respect to his Lordship, he did not care whether it was called discount or commission. The plaintiff went to the Company and asked what terms he should be put upon for introducing the light; and he was told "trade terms."

The RECORDER: The evidence does not support the particulars.

Mr. Cock, in reply to a juryman, said that the account was paid by Willis's Company on Nov. 2 last year.

Mr. WRIGHT: You promised that the matter should be settled as soon as the account was paid.

The RECORDER: You did not buy anything of the Incandescent Company. No contract was made with them; it was a mere introductory promise, and meant this: If you will push the sale of the lights, and will become our customer, we will give you the trade discount. The plaintiff would not come under the trade terms until he actually became a customer. He should therefore nonsuit him.

LAWFORD'S GATE (GLOUCESTERSHIRE) PETTY SESSIONS.

MONDAY, OCT. 15.

(Before Mr. F. TOTTELL, Chairman, and a Bench of Magistrates.)

PROSECUTION BY THE BRISTOL GAS COMPANY.

To-day Mr. R. T. Lucas, of Tudor Lodge, Sned Park, Bristol, was summoned by the Bristol Gas Company for having refused permission to an officer of the Company to examine the gas-meter on his premises, and also with having improperly connected the meter with the service-pipe.

Mr. BRITAIN appeared on behalf of the Company; Mr. DICKINSON represented the defendant.

Mr. BRITAIN stated that application was made by a collector, on the 18th of July, for payment of the gas account up to the 6th of June. The money was not paid; and another application was made on the 3rd of September. The account not having been settled, the defendant was served with the statutory notice that his supply of gas would be discontinued. As the money was not forthcoming, one of the Company's servants cut off the gas. After this the Company, having reason to suspect that the pipes had been improperly connected, sent an officer to examine the meter; but he was refused admission. The same man again called at the house, and was again refused admission. On another occasion a man was admitted, and found the supply-pipe connected from the meter, and 4200 feet of gas consumed. The summonses were accordingly taken out.

Mr. DICKINSON said the defendant possessed a number of valuable horses. During the summer months he was away from home, and (as was necessary) gave stringent instructions as to who should be admitted to the premises during his absence. The gas account was sent in, and was probably laid aside, Mr. Lucas being absent. Shortly after the gas was cut off, the money was paid; and then Mr. King (brother-in-law of the defendant), who had been left in charge of the house, thought that, as the account had been settled, they had a right to connect the service-pipe with the meter; and this was accordingly done. The reason the men were not allowed to enter the house was because Mr. Lucas had given such stringent orders to his servants about the admission of strangers during his absence; and the officers of the Company were all strangers except the last, who was admitted because he usually examined the meter.

Mr. BRITAIN expressing his willingness to accept this explanation, the case was dismissed; the defendant having agreed to pay costs, and given a promise that the offence should not be repeated.

Miscellaneous News.

THE HACKNEY DISTRICT BOARD OF WORKS AND THE LAYING OF GAS-MAINS.

STEAM-ROLLERS AND GAS-PIPES.

At the Hackney Town Hall on Thursday last, Sir DOUGLAS GALTON, K.C.B., held an inquiry on behalf of the Board of Trade, under the powers conferred upon them by the Metropolis Gas Act, into a dispute which has arisen between The Gaslight and Coke Company and the Hackney District Board of Works as to the laying of a gas-main in the area over which the latter body has jurisdiction.

Mr. DANCKWERTS (instructed by Messrs. Bedford, Monier-Williams, and Robinson, of 6 and 7, Great Tower Street, E.C.) appeared for The Gaslight and Coke Company; Mr. R. ELLIS (Vestry Clerk), Mr. LOVEGROVE (Surveyor of the Hackney district), and Mr. GROCOTT for the Board.

Mr. DANCKWERTS, in opening the inquiry, called attention to previous cases of a similar character, in which Kensington, Islington, and Chelsea were concerned, and in each of which settlements were come to. The piece of road in question in the present instance was in the Manor Road, Stoke Newington—from the Bethane Road down to Bouverie Road. They had at present an 18-inch gas-pipe which came from a westerly direction, and ended at Bouverie Road. What they wanted to do was this: They found the requirements of the inhabitants of the district necessitated a greater supply of gas; and they wished to continue this 18-inch pipe from the Bouverie Road to about opposite the Bethane Road. Roughly speaking, the distance was 650 feet. Along the Manor Road under each of the footways, they had a 4-inch gas-main; and along a portion of the road, as he had mentioned, they had an 18-inch main, which ended at Bouverie Road. This main was laid last year, he believed; and, of course, after receiving the consent of the Vestry under the Act of Parliament to which he should call attention later on. The pipe was placed at a depth of 2 feet below the surface of the road. The water-main was 3 feet deep at the Bouverie Road, and 2 ft. 4 in. at the Bethane Road end. The 18-inch gas-main proceeded along the south side of the road; and they merely proposed to continue it at the same depth. The position in which they could lay the pipe was extremely limited; it must be above the 30-inch water-main in the road. The Company, as far back as April 28 last, sought permission from the Vestry to extend the main; and they received a reply on May 10, stating that the Board could not consent to the proposal, unless the Company agreed that no part of the pipe should be less than 2 ft. 6 in. from the surface of the road. He (the learned Counsel) was strongly of opinion that the Vestry had completely mistaken their functions in this case. In their reply to this letter, on May 14, the Company said that the depth at which the Board required the Company to lay the pipe was entirely outside their experience; that it was a condition which they had never been required to carry out; that their standard depth in the roadway was 2 feet from the surface of the road to the upper side of the pipes; that the mains were equally safe from damage; that the roadway was less disturbed in the laying, and in any subsequent work that might be required; and that consequently consolidation took place more rapidly and effectually. On May 22, an answer was received, which stated that the Committee of the Board adhered to the resolutions set out in their letter of May 10, "unless your Company will hold this Board harmless for any damage which may have been done by the Board's steam-rollers should the main be laid at a less depth than 2 ft. 6 in." He (the learned Counsel) did not think the Board had any right to make such a stipulation, or have any regard to the steam-roller requirements whatever. He considered the steam-roller requirements were absurd with respect to this case. The Inspector might be aware that there had been a controversy between certain Vestries of London and The Gaslight and Coke Company with reference to the use of steam-rollers. Nearly all the Vestries had at some time or other attacked the Company—using the expression, of course, figuratively—in connection with the steam-roller question. In the case of *The Gaslight and Coke Company v. The Vestry of St. Mary Abbots*, Mr. Justice Field decided that, there being no statute authorizing the Vestries to use steam-rollers, they employed them at their peril; that this was not one of the modes of repairing roads contemplated by the Act of Parliament; that the Gas Company had the right to have their pipes under the roadway; and therefore that they had a right not to be wantonly injured by the Vestries. This decision was upheld by the Court of Appeal. The Court of Appeal laid down this principle—that the Vestry had their duty to perform, which was to keep the roadway in a condition of repair to bear the ordinary traffic; and that the only thing which the Gas Company had to consider in laying their pipes was—of course, subject to any express statutory directions, and to their own necessities—to lay the pipes so that they should be safe against the ordinary traffic which was to be anticipated on the road. The Court granted an injunction prohibiting the Vestry from so using their steam-rollers as to injure properly laid pipes of the Company; leaving, of course, the question of what was "properly laid" to be determined in each case. He only referred to this case because it had been dragged, so to speak, into this controversy by the Vestry; and he would show why they sought to impose this condition of 2 ft. 6 in. upon them. A number of cases with other Vestries were pending at the time the Kensington one was decided; and amongst others was that in which the Vestry of Chelsea were concerned. Nearly all of them, with one or two exceptions, accepted the decision in this case. The Vestry of Chelsea were at the time insisting upon pipes being placed at a minimum depth of 4 feet below the surface of the roadway. The Company negotiated with them, and entered into an agreement. They agreed to put down all their mains and pipes for the laying of which they had to go to the Vestry for their consent in the way determined by this agreement; the Company not admitting any right in the Vestry to refuse their consent on the ground of the depth at which they laid their mains. It was expressly protested there that there was no such right; the Vestry contending that they had the right. They agreed to abstain from asking for an injunction against the Vestry on these terms, and that they should lay their pipes at a minimum depth of 20 inches. He ventured to say there was as much traffic in Chelsea as in the district now in question; and yet the Vestry were fully satisfied with the depth of 20 inches, and had not only agreed to accept this, but that they would pay all damage which should be done to the Company's pipes, or that the Company might have to pay to others where any of the pipes laid at this depth were broken by the Vestry's roller. The date of this agreement was Dec. 3, 1885. Thereafter they offered to make a like agreement with the other Vestries. But the Vestry of St. George's, who had also a dispute with the Company, which stood over pending the decision of the St. Mary Abbots case, decided to go on with the action; and the matter was accordingly tried before Mr. Justice Grove and a special jury—the result being again in the Company's favour, and they obtained an injunction against the Vestry upon the same principles as were down in the Court of Appeal in the Kensington case. The Vestry of St. George's were not satisfied with this; and they went to the Divisional Court, and tried to raise the controversy again, but failed.

So that in four separate Courts the Company had established their views against the Vestries. Still, this old controversy would again and again crop up, he could not help saying, much to the detriment of the ratepayers of the Metropolis. He believed the Marylebone Vestry tried to get some legislation upon the subject; but they failed. Returning to the correspondence with the Hackney Board, he said the Company wrote to the Board on May 22, expressing regret that the Committee adhered to their resolution of withholding their consent to the Company laying the main unless they placed it at the depth of 2 feet 6 inches, and pointing out that they were attempting to impose a condition which the Company were advised was quite outside the powers of the Board. If, the letter continued, the Vestries were to be at liberty to fix the depth at which mains were to be laid, it would become an impossibility for the Company to carry out these obligations; and if they were to understand that the Committee refused permission unless they agreed to this condition, the Company would have no alternative but to apply to the Board of Trade, which would be an expensive and somewhat lengthy proceeding. It was obvious, the learned Counsel remarked, that the persons who were best acquainted with the methods of laying pipes were gas companies' advisers; and they had to bear in mind all the statutory obligations which they had to observe in connection with the supply of gas and the laying of mains. The Company were obliged to supply gas at a particular pressure in every house; and therefore it was of great consequence that the mains should be so placed as to enable them to satisfy these statutory obligations. There were something like 30 parishes in London; and every surveyor in connection with these parishes had his own idea as to the depth at which pipes should be laid, with a view especially to the use of these excessive steam-rollers. Some of them, he believed, went in for a minimum depth of 6 ft. 6 in.; some, 4 feet; others, 15 inches and 20 inches; and some 2 ft. 6 in. If the Company were to observe all these requirements, it would be impossible for them to carry on their business and to satisfy their customers. It was essential that they should be able to get at a gas-pipe readily; and if a pipe was laid deep, it required a very much longer time to get at it, and there was necessarily a greater disturbance of the surface of the road. If a leak occurred and the pipe was laid too deep, the discovery of the escape was very much later, and the gas penetrated in all directions, causing explosions and dangers which did not occur when the pipes were not placed so low. Experience showed that all the pipes which had been laid for long periods in the Metropolis were safe from all ordinary traffic; and it had been shown that the larger pipes—these 18-inch pipes—were practically safe against any weight that could be brought upon them. It was impossible to crush them, so long as they were evenly laid on a good bed. With small gas-pipes, they had discovered that there was really no depth at which they would be safe from steam-rollers if subsidence occurred, because the nature of the soil of the streets of London was very often bad. Even if the Vestry had the right to make these requirements—

Mr. ELLIS (interposing) observed that the Vestry had not said they had the right to determine the depth.

Mr. DANCKWERTS replied that the Vestry made it a condition of their consent. Even supposing the Vestry had the right to make it a condition of their consent, it was in this case an absurd requirement on their part; and it became all the more absurd when they had regard to the particular circumstances of the case. Here they already had a pipe in the road at a depth of 2 feet; and the Company only sought to continue it for a very short distance. Were they to be compelled to suddenly descend to a greater depth, and consequently have to introduce all sorts of "dodges" in order to enable them to do it? They had to go to the Vestry in connection with this matter under the 109th section of the Metropolis Management Act, which required them to give notice to the Vestry or Board before breaking up the surface of the road. The sole object of this requirement was that the Vestry should, if they thought right, take precautions for the safety of the public while the streets were being broken up, and also have an opportunity of seeing that the surface was properly reinstated. And then it was provided that "no gaslight company should at any time break up or open any such pavement, surface, or soil for the purpose of laying down any new mains or pipes without the consent in writing of the said vestry or district board." Therefore, all they had to get was the consent of the Vestry to the breaking up of the surface of the road. The Company could lay the pipes at their own risk; but the Vestry must not break the "properly laid" pipes. By the decision in the Court of Appeal, they had only to have regard, in laying pipes, to the ordinary traffic. Therefore, he contended the Vestry had no right to dictate as to depth; they had no right to make it a condition of their consent that the pipes should be at a certain depth. The Acts of Parliament gave the Company the power to break up the streets and to lay their pipes under them; and all the Vestry had the right to say was that to-day or to-morrow was an inconvenient time to break up the surface, and some other period would be better. It was simply in breaking up the roads for the first time that consent had to be obtained. Once the pipes were laid, the Company had merely to give three days' notice before opening the road. The Vestry might just as well dictate the metal of which the pipes should be made, or their size, or that the pipes should be bedded in this or that way, or any other conditions which the ingenuity of Vestries was equal to suggesting. The Metropolis Gas Act of 1860 gave the Home Secretary the power of saying that the Company could lay their pipes without the consent of the Vestry; but by the Act of 1868 the Board of Trade had been substituted for the Home Secretary. Now, they refused the authority of the Board of Trade to lay down this pipe without the sanction of the Board. The learned Counsel then referred at length to the 50th section of the 1860 Act, which, he said, compelled them in such cases as this to go above the water-pipes; and he afterwards quoted various portions of the judgments in the steam-roller cases to which he had previously alluded.

Mr. ELLIS observed that before witnesses were called, he should like to say that his Board did not consider this was a question calling for scientific evidence. He indorsed almost every word which the learned Counsel had said respecting the cases which had been decided on the steam-roller question. A very ominous observation was made by his friend when speaking of the laying of gas-pipes. He used the words "one inch." Supposing the Company were intending to put the pipes in the ground only 1 inch, did they contend that they had a right to do it if they gave the Vestry the statutory notice? If this was so, it narrowed it to a very small limit. When the Company went to the Vestry to obtain their consent, they naturally, in the interest of the public and the ratepayers, said they must see that what the Company were going to do would not damnify the public in any way. The Company said it is not a question of damage in any shape or way, but a mere question of assent or dissent. The learned Counsel had not read the last two letters which had passed between the parties, and all the Vestry had done throughout was to protect the public as much as they could. If the Company would hold the Board harmless from any damage done by the steam-roller if the main was laid at a less depth than 2 ft. 6 in., then they would give any assent required. But the Company studiously refused to do this.

Mr. DANCKWERTS: Because you have no right to impose upon us any such condition.

The INSPECTOR said he thought the contention was that the Company were bound to lay the pipes at such a depth as would make them perfectly safe against ordinary traffic; but under the judgment of the Court of Appeal, they were not bound to make them good against heavy or other steam-rollers.

Mr. ELLIS quite agreed with the interpretation of that point. The Company, he went on to say, considered that a depth of 2 feet was quite sufficient; but they would not agree to the Vestry's condition—to hold them harmless for any damage done by the steam-roller to the pipe, if laid at this depth. If they would not agree to this, then the Vestry said they must go to some higher authority for permission to open the street. He did not think any of the Metropolitan Vestries or Boards would take that risk in future, considering that they had had to pay for the breaking of these pipes many times during the last few years.

Mr. DANCKWERTS observed that they were not bound to pay for the damage if the pipes were not laid properly.

The INSPECTOR said it seemed to him to be necessary that the reasons should be stated why the Board objected to give their consent.

Mr. DANCKWERTS said that all he required was a simple authority from the Board of Trade to lay the pipe. So far as he knew, the Vestry undertook no legal responsibility whatever in giving their consent.

Mr. ELLIS remarked that the correspondence showed plainly why the Board objected to give their assent. If the Company were satisfied that 2 feet was a sufficient depth, then let them take the responsibility. If the Board of Trade thought their contention unreasonable, that the main should be laid 6 inches deeper, when the Company were satisfied there was no danger, then there was an immense amount of responsibility taken off the District Board's hands.

Mr. DANCKWERTS: None at all.

Mr. ELLIS said he did not see why the Company could not come to an arrangement with the District Board the same as they did with the Chelsea Vestry.

Mr. DANCKWERTS expressed his readiness to execute at once an agreement in the same terms.

Mr. ELLIS said the Board would be willing to take the whole of the agreement with the exception of some few points.

Mr. Corbet Woodall was then called, and examined by Mr. DANCKWERTS. He gave it as his opinion that 20 inches was an ample covering for gas and water pipes. At this depth they were quite safe from damage from ordinary traffic; and any increased depth added very much to incidental differences attaching to them. He had seen the road in question; and the 18-inch main laid at a depth of 2 feet would be absolutely safe. The only cause that could lead to damage would be a faulty foundation due to a settlement upon a deep sewer or anything of that sort, which would certainly not be provided against by an extra 6 inches. It would have to be a considerable settlement to endanger an 18-inch main. He might perhaps mention that some few months ago he saw a trench opened, he believed it was in Leadenhall Street, where the ground was absolutely hollow for a length of 14 or 15 feet, and a width in some places of 10 feet. The whole of the surface was carried partly by the arching of the concrete, and partly by the gas and water pipes underneath. This had happened through filling in an entrance into a main sewer. There had been a settlement, which had loosened the joint of the water-pipe; and the escaping water had caused the earth to settle round about. It was quite impossible to provide against this kind of thing. It would be extremely embarrassing to have to lay some mains at a greater depth than others. It was essential that gas-pipes should drain in one direction; otherwise there would be an accumulation of moisture, which would cause an obstruction to the passage of gas. They must therefore be laid with a fall in one direction; and at the end of these inclinations receivers must be placed to take the deposited moisture. The multiplication of these receivers was a decided objection. It was desirable to keep the gas-main as near the surface as was safe. Where pipes were laid at too great a depth, leakage must occur at one point, and make itself evident at some 100 yards away. He could not remember a single case in which a pipe had been broken by ordinary traffic. In his opinion, the responsibility of laying the pipes should rest entirely with the Gas Company. The cost of the extra depth of 6 inches would be a very small matter indeed, and could not weigh for a moment against the other questions of safety to the public, and the convenience of the conduct of the business of the Company. It was, of course, most important to the Company to secure the safety of their pipes. The traffic in this particular road was simply that of a respectable middle-class neighbourhood. To break such a pipe as it was proposed to lay would require a very considerable strain.

Cross-examined by Mr. ELLIS: He had never given evidence on behalf of road authorities. His experience had been entirely on the part of gas and water companies; nevertheless, he tried to look at these questions fairly and impartially. If the pipe in question was properly bedded, and had a covering of 20 inches, he should not be at all afraid of the steam-roller. He had no objection to this opinion going down as his evidence for use on any future occasion.

Mr. ELLIS remarked that Mr. Danckwerts had just made a suggestion to him; but probably it would be advisable for him not to fall in with one suggestion or the other. If on the consideration of these matters and the report he should be able to lay before his Board, they thought the case was sufficient to leave where it was, and decided to leave it in the Inspector's hands, then he would communicate to the gentlemen on the other side. If not, there would have to be another sitting he supposed. He wished to remark that, in opening the case, he said on the part of the Local Authority that they wished—as his friend put it—to shunt the matter on to the Board of Trade; but that was not the exact object. Their desire was to satisfy themselves and the public that everything had been done to protect their road in the position they were placed in.

The INSPECTOR remarked that if it was necessary, he would shortly name another day for the continuation of the proceedings; but if it was not found to be essential, he would then report direct to the Board of Trade.

THE PUBLIC LIGHTING OF FLEETWOOD.—A meeting of ratepayers was held in Fielden Public Hall, Fleetwood, on Monday evening last week, to hear the report of the deputation appointed some time ago to inquire into the cost and methods of lighting in other towns. Mr. T. Seed presided, and was supported by nearly all the members of the Board of Improvement Commissioners. Mr. Tildsley, Clerk to the Commissioners, read the report, which gave many interesting details concerning the cost of electric lighting. One conclusion the Committee had arrived at was that in a town like Fleetwood, where the cost of gas is more than 4s. per 1000 cubic feet, the introduction of the electric light would ensure a considerable saving. The Committee recommended that immediate steps be taken with a view to learning the cost of introducing the electric light or water gas. It was resolved—"That the Improvement Commissioners be requested to take into consideration the recommendations made in the report, with a view to the introduction of the electric light or other light into Fleetwood."

GLASGOW CORPORATION GAS TRUST.

THE PROPOSED PURCHASE OF THE PARTICK, HILLHEAD, AND MARYHILL GAS-WORKS.

A Special Meeting of the Town Council of Glasgow, sitting as the Gas Trust, was held last Thursday, for the consideration of the minutes of the Gas Committee bearing upon the purchase of the business, works, and plant of the Partick, Hillhead, and Maryhill Gas Company. The recommendations of the Committee, briefly stated, were as follows:—(1) The holders of the 5½ per cent. preference stock (£30,000), to be paid the amount of their stock, and 10 per cent. premium. (2) The holders of the ordinary stock (£99,300), to be paid the amount of their stock, less 10 per cent. discount. (3) The Gas Trustees to assume the debenture debt and the other liabilities of the Company, and to be entitled to all assets.

Lord Provost Sir JAMES KING moved the adoption of the minutes; and in doing so said he would not go into detail, or into any of the figures, with which he had dealt at the private meeting of the Council on the preceding Thursday. He explained that the bargain would not be binding until it had been accepted by the shareholders of the Company; and therefore he did not think it was desirable that they should show their hands by stating fully all the facts and figures which had weighed with the Committee and also with the Company after receiving the report of the Committee in coming to their decision. He might say that none of them would desire to make a purchase of the concern in question by itself; but they did think that, in the event of the boundaries of the city being extended, the presence in their midst of another authority having powers, like themselves, of supplying gas to the community, would be very objectionable. They considered it was desirable that it should come into the hands of the Corporation, and that the whole supply of gas throughout the entire city should be undertaken by the Council. It seemed to them there was no time more favourable than the present for carrying through such arrangements; and while the sum which had been conditionally agreed upon was large, and a very liberal one, they did not think there was any prospect of its being obtained compulsorily or by private agreement afterwards, on terms more favourable—if, indeed, it could be obtained on equally favourable terms. The sum which it was proposed to give was £172,870, of which £50,500 did not go into the hands of the Company, but would be applied in taking up the debentures from time to time as they fell due. The amount to be paid to the Company, therefore in the event of the bargain being carried out, after the Annexation Bill was passed, would be £122,370, which they could divide in the form they thought best. Besides paying this sum, they were to take the responsibility of £4700, which was being expended in the improvement of the works and the erection of a new gasholder, and to allow the Company £500, being the balance of their profit and loss account subject to the audit of their professional auditor. On these terms, the Committee met with the Directors of the Company; and he (the Lord Provost) believed he could say the whole of the Corporation were all but unanimous in recommending that the bargain should be agreed to, so far as they were concerned. Reserving to himself the right of going into figures afterwards, he formally moved the approval of the minutes.

Ex-Bailie URE (who, as the Convener of the Sub-Committee on Works, was one of the negotiators with the Gas Company) also reserved to himself the right of explaining afterwards.

Lord Dean of Guild WALLS remarked that disputes had previously occurred as to the right of making any reservations; and he thought all statements should be completed there and then.

Mr. CALDWELL seconded the motion.

Bailie McFARLANE said that he had been given to understand that a good part of what was said at the private meeting of the Council had gone forth to the public, and had been freely discussed. Under these circumstances, he would request the Lord Provost to go into his figures at that stage of the proceedings.

Preceptor OSBORNE asked where a report of last meeting's proceedings had appeared, as he had not seen it.

Bailie McFARLANE replied that the proceedings had gone out to the public; and some of the objections which he had made had appeared in print. Who was responsible for this he could not say. Those remarks had been the subject of conversation in the city; and therefore it seemed they were pretty widely known. He then moved that the minutes be not confirmed, on the ground (1) that it was unnecessary to acquire the Partick, Hillhead, and Maryhill Gas Company's undertaking; (2) that Mr. Hawkley's report on the subject was not a sufficient basis for negotiation; (3) that the terms proposed were excessive; and (4) that the acceptance of the terms would cause a serious loss to the Gas Trust annually. So far as the details of the agreement were concerned, he had no fault to find. The first point which he wished to take up was whether or not it was necessary for the Corporation as the Gas Trust to acquire the works. As a general principle, it was desirable that there should be only one gas undertaking supplying gas to the City of Glasgow at large. There came, however, the serious question whether they ought, as a matter of policy, to continue to extend their gas-works as they were doing. He considered they should now draw the line as they saw fit. It came to be a question whether they should be like some huge octopus throwing out its tendrils on every side, and driving all into its capacious maw. As a matter of fact, they did not require the works in question. Referring to the Gas Company's balance-sheet of 1888, he pointed out that the account for coals last year was £300 less than in the preceding year, and that there had been an additional £3400 worth of gas produced. While £300 less had been paid for coals, yet there had been no substantial reduction in the cost of the higher priced coal. Then there was the fact that the total income had been lessened to the extent of £1600 or thereby, in consequence of the reduction of 2d. per 1000 cubic feet in the price of the gas. Comparing the illuminating power of the Corporation gas and that of the Company, he said the standard in Glasgow was 23·1 candles; whereas the standard of the Company's gas was from 17 to 18 candles, and it had been as low as 14½ candles. On the question of assets, he showed that the works, pipes, and meters of the Company were valued at £180,000; and he pointed out that Glasgow was already furnished with pipes quite sufficient to supply in large measure all the demands that might be made upon them. Another strong argument which had been used, he said, was that they were only being called upon to pay about £23 per million cubic feet of gas made; whereas the price paid for the old Companies' works was from £39 to £40 per million feet; and the price recently paid for the Edinburgh and Leith gas undertakings was about £34 per million feet. But in comparing the concern under consideration with the works taken over in 1869, they were comparing things that were entirely different. When they acquired those works twenty years ago, they got a huge monopoly into their hands; and if they considered the different rates for gas they would find that the relative prices were against the Maryhill works. Again, looking to the financial position, if they included the cost of concentrating the work at Dawsholm, they would require to spend £200,000. Against this, however, they had to consider the revenue, which last year amounted to £31,000, and which left a gross revenue of £9200. During the present year, however, they had reduced this by £1800, by taking 2d. off the price

of gas—making the surplus £7400. After allowing for depreciation and other outlays, the sum of £2900 was left to pay the interest on the £200,000, which was less than 1½ per cent. On these and other grounds, he submitted his amendment.

Baillie GRAY seconded the amendment; and in doing so, took exception on general grounds to the whole question being brought up now. In the first place, he did not consider that the Boundaries Committee had any business in going into the matter without a remit from the Town Council; and he further thought that the whole procedure in connection with the matter had been far too hasty. As to the terms of the bargain, it was proposed to take up the 19,800 ordinary £5 shares, which had paid no dividend for some years, except in 1885, when they paid 2½ per cent. Now the valuation which the shareholders themselves placed on the stock last year was £37,720. After the evidence of Mr. Osborne before the Boundaries Commissioners as to the probability of the works being taken over, the value rose to £76,680; and now it was recommended that they should pay £89,870. In regard to the preference stock, there were 6000 £5 shares, valued last year at £27,750, and for which it was recommended that they should pay £36,000. In addition, they were not sure of the debts that were to be assumed. They had not the accounts of the Gas Company before them; and they had very little information to enable them to come to a proper decision on the subject.

Mr. W. WILSON supported the amendment. He thought that to carry out the proposal of the Committee would be a serious blunder; and he referred to the rise in the price of the Company's stock from 40s. to about 90s. per share. The shares he believed to be in the hands of a few "wire-pullers," who would be the gainers by the transaction. They were about to spend £150,000 in extensions at the Tradeston Gas-Works, which he considered was enough. He was sure that while they wished for annexation, they could not but feel that they might pay too much for it; and he had therefore much pleasure in supporting the amendment of Baillie M'Farlane.

Mr. PATON observed that the question under consideration was, of course, one in which it would appear that they were endeavouring to bring all round, so as to accomplish a certain purpose; but if those gentlemen opposed to the bargain had paid the same attention to it as the Gas Committee, they would have come to a like conclusion. They had to keep in mind that, after all, it was to a large extent buying the goodwill of a business—the annual revenue being something like £36,000 or £37,000—and a business, too, in the best part of the city. It was a quarter of the city where the quantity of gas required was likely to be larger than in any other part; and consequently they might reasonably expect that the annual revenue would be doubled in a few years. The Partick Company could give advantages to customers which the Corporation, bound by statutory regulations, could not do. The result was that the Company were getting the gas supply in almost every new building, simply because they could provide the pipes, which the Corporation could not do. He had listened with some astonishment to the remarks of Baillie Gray, when he said at the private meeting that the Committee went further than they were authorized to do. While he had a little sympathy with that remark, they ought to recognize that the Committee on that occasion acted for what they considered to be the very best interests of the city. They knew that the matter was one which was in its initial stages, and when it could not be talked of publicly. It might or might not have been a little irregular at the beginning; but it must be admitted as having done very good work. It also seemed as if Baillie Gray said that, on account of the action taken by the Corporation, the value of the Gas Company's shares had risen from 41s. or 42s. to 90s. He considered that Baillie Gray was not acting fairly towards the Council in the matter. There were other causes for the rise in the value of the stock besides the action of the Corporation. It was well known that in recent years the Partick Company had encountered serious difficulties, and had been unable to pay a dividend; but these difficulties had now been very largely surmounted, and last year the Company, he was informed, actually paid a dividend of from 4 to 5 per cent. The principal cause of the rise in the value of the shares was that the Company had now emerged out of its difficulties, and the shareholders and the public thought there was a fair prospect of the concern in the future being able to pay a good dividend. They knew very well that if annexation was to take place, they would have to give the Company a *quid pro quo* in some manner or other; and he thought it would be better if the Town Council took advantage of the present favourable opportunity than go to arbitration.

Baillie SHEARER objected to the proposed purchase; and he expressed a fear that they were paying too dear for their "whistle" in connection with the extension of the boundaries.

Baillie SIMONS, referring to the terms on which they were to acquire the works, remarked that Mr. Hawksley's report had not been founded on the present market value of the shares, but on ten previous balance-sheets—not one, as Baillie M'Farlane would lead them to infer. After the Annexation Bill passed through Parliament, they would be compelled to buy the works; and he would like to know if they could possibly make more favourable arrangements under compulsory powers than at present. Were they to acquire the works, they would be a source of profit, apart altogether from the question of smoothing the way for annexation.

Several other members having spoken, chiefly in support of the proposed purchase being made,

The LORD PROVOST said that if a decision were not come to at that meeting, the question would have to be decided by the new Council, which was not desirable. As to the winding up of the Company, he observed that the expense would probably not be more than £200, unless there was litigation, and that could only be between the different classes of shareholders, and not between the Company and the Corporation. Replying to a question, his lordship went on to say that the purchase depended entirely on the proposal for the extension of the municipal boundaries being carried. He pointed out that the gross profit of the Company last year was £14,100. If from this they took off £2500 paid in respect of debentures, and £1650 for interest payable on the £30,000 of preference stock, they would have a sum of nearly £10,000, which they could allocate as they liked—between depreciation on the one hand and to the shareholders on the other. The price to be paid, he did not think unduly large. It was not a purchase he would recommend apart from annexation; but if the Annexation Bill was passed, a settlement of the question on the terms proposed, while a full and liberal one towards shareholders of the Company, would not, he thought, give the Corporation cause of regret.

The motion was agreed to by 30 votes against 9.

The LORD PROVOST subsequently stated that they were not under any obligation whatever to go to Parliament in the present year to sanction the terms of purchase agreed upon. If they decided not to go on just now, the Directors of the Company could have no ground of complaint against them; but he would like it to be understood that, in the event of the Annexation Bill failing, they would, of course, not continue with the application. Taking all things into consideration, however, he was himself in favour of serving the notice to go on this year.

Mr. URE agreed with the Lord Provost, and said that in the works Committee several re-arrangements had already been kept back with a

view to seeing whether they were to have possession of the works and it was putting them to considerable inconvenience.

Some further discussion took place; and it was eventually agreed, that a Private Bill to sanction the purchase should be promoted this year, only contingent on the passing of the Boundaries Bill to be proposed by the Government.

THE CHARGES IN CONNECTION WITH THE HALIFAX GAS COAL CONTRACTS.

On Monday last week, Mr. Alderman Riley's Solicitors forwarded to the Mayor of Halifax (Mr. Alderman J. Booth) a draft of the indemnity which they proposed should be given to Mr. Riley by the Corporation. The draft was revised by the Town Clerk, and returned amended. The main difference between the terms of the indemnity as drawn by Mr. Riley's Solicitors and that given to Mr. Fox is, we believe, that Mr. Riley seeks to confine his accusers to proving that he has corruptly received money by way of commission or bribe on coal or other goods purchased by the Halifax Corporation for the gas-works. This, it is thought, was hardly likely to be entertained by the Town Council; and it is understood that the Town Clerk has altered the form of indemnity. The matter is to come before the Council at a special meeting to-day, when a proposal may be made authorizing the Mayor to sign the deed of indemnity to be given to Mr. Riley.

The Mayor, addressing last night week a meeting in connection with the municipal elections, alluded at some length to the "gas scandal," with the object of justifying the action of the Council in giving an indemnity to Mr. Fox. Proceeding, he said Mr. Fox must now prove his case or bear the brunt himself. He believed the bulk of the people expected that, these charges being put in the form of a very strong libel, those concerned would take action. But they knew that Mr. Carr would not fight—he had said he would not. They had also had a letter from Mr. Wrigley, who was implicated as the coal agent who had contracted to supply a particular kind of coal and had sent a different quality, and he said he would not fight. He (the Mayor) thought that as time went on they would find that none of the accused persons would fight. Then the question arose, Was the matter to quietly subside because these people would not take action? He thought not. There were other resources open. He thought it would be the duty of the Corporation to sue Mr. Wrigley for the difference in the value of the coal contracted for and that supplied. That was one step. He thought another would be to ask the Lord Chancellor to send down a Commissioner to examine people on oath, and take evidence that would get to the bottom of the whole matter. If the thing was unsound and corrupt, let it be known. He (the Mayor) would certainly do everything he could to "bottom" it thoroughly. The people of Halifax might feel assured, and take it from him, that if it was possible to find out and get clear knowledge of what had taken place, he would do everything that lay in his power to accomplish it. In a subsequent speech the same evening, his Worship suggested that the Corporation ought to adopt a Standing Order providing that no member should occupy the position of Chairman of a Committee for more than three years. If they had passed such a resolution half-a-dozen years ago, the members of the Gas Committee would not have had such blind confidence as they had shown.

At a meeting held last Thursday evening, Mr. Binns, a member of the Gas Committee, said that when the charges were made Mr. Bairstow raised the question in the Committee, and insisted on the Committee being informed of them. They were peremptorily told by the Town Clerk that they had handed the matter over to a Committee of three gentlemen, and now had nothing to do with it any more than the other Committees. Therefore they thought they were politely "shut up," because the Town Clerk was their legal adviser. The Mayor had gone about and done just as he pleased—investigating what he thought proper. There was a policeman placed in the office at the gas-works. The Committee did not know, until the Council meeting a few days previously, who was to be charged, and therefore they had indeed been "dumb dogs." The Committee included gentlemen above suspicion, and they hoped everything would be done to bring to light any malpractices which had been going on. They had been kept in the dark, and had to wait the unravelling of events; and they therefore thought their best policy was to keep their mouths shut until they heard the charges against them. A long array of questions, all on the "gas scandal," was sent up in writing for Mr. Binns. Replying to them, he said he did not know of any commission being paid to the Chairman of the Gas Committee. He was not aware, until the statement was made, that every truck of coal was not weighed. He had seen the weighing-book, the entries in which went back for two years, and he did not think that there were three where the coals were recorded as being under weight. He explained that the difficulty about weighing every ton of coal coming into the works arose through the delay and inconvenience caused to the Railway Company in shunting. As to testing the quality of the gas, the Committee at their last meeting appointed Mr. Ackroyd, Borough Analyst to take two observations a week, and report them to the Committee. Tests of the quality of the coal had been made by Mr. Carr, and these tests, when required, had been laid before the Committee. Mr. Carr, for some reason, had abstracted a number of pages from the test-book. The Committee had not given any orders for the weighing-machine to be mended, and he was not aware that it had been out of order for three months. He was not prepared to say they had received an inferior class of coal to that specified in the contracts. His own honest conviction was that not a single pennyworth of coal went into the gas-works but what was of legitimate market value.

Mr. Bairstow was present at another meeting held on the same evening, and also alluded to the subject. He explained that, though a member of the Gas Committee, he had not, on account of a personal difference with the Chairman, taken a very active part in conducting the works. The late Manager (Mr. Carr) thought fit one day to "interview" him (Mr. Bairstow); and he gathered certain information from Mr. Carr. After hearing his explanations, he asked him if that was all he had been guilty of; and on being assured that it was, he said, "If that be so, I should be the last man in the world to visit the sins of the whole country upon your head, if there's nothing else to be charged against you." He added that, as the Mayor had undertaken that Mr. Carr should have an indemnity provided he justified himself, he (Mr. Bairstow) promised to help the Mayor in paying any expenses that might be incurred. Other things had arisen since then; and the meeting would not expect him to say more upon the subject. Being asked whether, on the occasion of the construction of the last gasholder, Mr. Carr did not get £700 in addition to his salary, Mr. Bairstow said he had not the figures at that moment, but Mr. Carr did get a commission. ("Shame.") No; it was not a shame. ("He was a servant.") But Mr. Carr did not go into the service of the Corporation to construct a gasholder. He worked entire nights on the plans for it. He should say that by employing Mr. Carr on the work the Corporation saved 2½ per cent. on the value.

Alderman Ramsden, who was one of the three members of the Investigation Committee (the other two being the Mayor and the Town Clerk), also spoke at a public meeting on Thursday evening. He said it must be remembered that as yet they had only suspicion, accusation, and remarks

about certain persons as to certain things being done; but these were very serious indeed, and, as he thought, very well based. Beyond this he thought it would not be fair for him to go. The inquiry they had to undertake was to ascertain where the guilt lay, and, if possible—and surely it was possible—to bring forth sufficient evidence to satisfy all of them as to the truth of those accusations. If the statements were untrue, those who were innocent should be completely cleared in the eyes of the public, and those who were guilty should be punished as they deserved. Accusations of a grave character had been made; and it was naturally expected that the persons who were accused would in some way or another proceed to defend themselves. If they failed to do this, then the difficulty arose as to what should be done. He was of opinion that not all those who were accused would enter the Courts of Law, where there might be an opportunity of ascertaining the guilt or innocence of certain persons. Failing this, he still thought “the resources of civilization” would not be quite exhausted as to the means of getting at the truth. Charges had been made of supplying to the Corporation a smaller quantity of goods, and goods inferior in quality, to those which had been bought and paid for. Surely there was some process in the law by which this could be proved, and, if proved, some method by which at least there should be disgorgement—a giving up of that which had been unlawfully obtained. But there were other ways, even if this course should not be resorted to. There was said to have been an interference with the property of the Corporation at the gas-works—an interference with books; and surely this was an unlawful thing. If books containing entries which should be valuable to the Corporation had been tampered with, even to the extent of cutting out the leaves, there were means by which punishment might be accorded to the persons proved guilty. Throughout England this matter was looked upon at the present time with extreme anxiety, because in other boroughs charges were being made, or would be made before long, quite as serious as those in Halifax. For himself, this scandal was about the most painful thing he had ever had to do with.

Another member of the Gas Committee (Mr. Bramley) told his constituents that Mr. Carr served them faithfully for 13 years, so far as they knew, and had the full confidence of the Council and Committee. The way in which he had been held up to the public was surely a great punishment to him; and if he did not go into a Court of Law to clear his character, he (Mr. Bramley) was not going to blame him. The course that was being pursued—providing indemnities and finding work for lawyers—was a method of which he did not approve. So far as he could see, it was not leading to any satisfactory result; and the probability was that some other course would have to be adopted. Any reasonable and just course he would support with all his heart.

At a meeting last Wednesday evening, Mr. Brook, who was also on the Gas Committee, said he was informed that the Mayor and Town Clerk had gone to London to make some inquiries, and probably to ask that a Commissioner might be sent down to investigate the matter. He had been one of the three appointed to superintend the work during the time Mr. Carr was away from home, and though at the works almost daily, and having everything open to his investigation, he never observed anything that led him to think affairs were not straight and fair. The Gas Committee had been almost in the hands of the Chairman and Manager during the past ten years, and he thought it was a fault for a Chairman to remain so long on any Committee, as it did not give the other members an opportunity to rise to such a position. To his mind matters would turn out better than was expected. The contracts for coal, so far as he was concerned, had been gone through fairly, and the opinion of experts taken.

ROCHDALE CORPORATION GAS SUPPLY.

THE RECENT CHARGES IN CONNECTION WITH THE COAL CONTRACTS—THE PRICE OF GAS.

At a Ward Meeting held, in view of the forthcoming municipal elections, at Rochdale on the 11th inst.—Mr. J. LEACH in the chair—the subject of the coal contracts of the Corporation Gas Committee, which, as will be remembered, recently gave rise to some discussion in the Council, were referred to.

Mr. PARKER said he thought some explanation was due from him as to the very disturbed and excited state of public feeling which had been caused in the town by Mr. Evans making known at a public meeting a private conversation which had taken place between that gentleman and himself respecting the town's affairs. On meeting Mr. Evans, he (the speaker) told him that he agreed with the Council in everything they had done since he joined them, saving the acceptance of the coal contract recommended by the Gas Committee. He had been greatly blamed for saying what he did to Mr. Evans; but he was prepared to defend everything he had stated to him. The only thing that needed explanation was the difference in price between the coal the Committee had decided to buy and that which they might have purchased, and to which he had drawn attention. The prices charged by the Wigan Coal and Iron Company, whose contract the Committee had accepted, were 9s. 3d. and 7s. 6d. per ton; whereas the prices he had alluded to were 7s. 3d. and 6s. 6d. The average prices of the two lots of coal were 8s. 4d. for that of the Wigan Coal and Iron Company, and 6s. 10½d. for the other. The cheaper coal would produce 9240 cubic feet of 18-7-candle gas per ton; and if its price and illuminating and producing powers were considered, it would be found to be rather over than under 1s. below the cost of that of the Wigan Coal and Iron Company. The Chairman of the Gas Committee had referred to some coal which was 11d. a ton cheaper than that accepted by the Committee, and had said that this coal would only produce 17-candle gas. He (Mr. Parker) adhered to his original statement that that coal would produce 9300 cubic feet of 18-62-candle gas per ton. In the Council Chamber, Mr. Alderman Baron stated that an increase of one candle in the illuminating quality of the gas made was equal to a difference of 2s. 6d. per ton in the price charged for the coal. If this were so, the Gas Committee had refused to accept a coal the value of which was 7s. 6d. a ton more than that of the Wigan Coal and Iron Company, because it would make 9860 cubic feet of 21-candle gas per ton; and by so doing they had caused a loss of £1750 to the gas consumers of the borough. This was apart from the loss of 1s. per ton on the 20,000 tons of coal previously mentioned. He (the speaker) had practically been forced into this matter by the remarks made by Mr. Evans at the public meeting; but he certainly still adhered to everything he had said before.

Mr. Duckworth criticized the action of the Gas Committee in proposing an increase of salaries, and said he could only account for the proposition on the ground that the Committee were flush of money. It would be better if the Committee had less money to spend, and if the townspeople were supplied with gas, not at cost price, but at a price nearer its price to the Committee. If the reduction in the price of gas could not be obtained without increasing other rates, then let those rates be increased, so that the people might know what it was they had to pay for. At present the Committee were subjected to a strong temptation to use money in a way they would not do if they had less money to spend. He did not charge the Committee with either wilful waste, indiscretion, or

want of judgment; he was simply pointing out something to which they were liable by force of circumstances. Shopkeepers were compelled to do their business after dark, and to use gas for attraction and display as well as for business. Gas was an absolute necessity to them; and yet in Rochdale they had to pay almost double what they ought to be charged for it. This was, to his mind, a very great injustice.

Alderman PETRIE said he had thought Mr. Parker had not another word to say on the subject of the coal contracts; but he chose to stick to his text, and had again asserted that there was a coal which was very much cheaper than the coal the Committee had bought, and that it would produce quite as many thousand cubic feet of gas per ton. Well, Mr. Parker took care not to mention the name of the coal or that of the people who sold it. Mr. Parker had not told the Committee where it was to be obtained; and he (the speaker) denied the truth of the statement that there was such a coal as he mentioned at the price, producing as many feet of gas per ton. It was utterly false; there was not a word of truth in the statement. Wondering how Mr. Parker came to say such a thing, he obtained a clue to it from another statement Mr. Parker had made. He spoke of a coal to which the Committee thought he was referring—the coal that was 11d. a ton cheaper than the coal they had bought—and stated that this coal would make 19-candle gas. He said so because he had seen it advertised. Well, to take an advertisement of what a coal would do was simply absurd; and if Mr. Parker knew how to go about the business rightly, he would never dream of doing that. The information the Committee had was that which the proprietor of the coal himself gave. He told them the number of thousand cubic feet of gas it would make, and said it would yield gas up to 17-candle power. When choosing coal, taking its proprietor's statement as to what it would do, and then testing it, the Committee found that in nine cases out of ten the coal did not quite justify the statement. In fact, it often came a long way below it. But in this case, even on the proprietor's statement that the coal would produce 17-candle gas, it was put out of the books altogether; it would not do for the Committee.

Alderman SIMPSON said he could not endorse Mr. Duckworth's statements as to the price charged for gas supplied by the Corporation. The object of a recent public meeting was to urge the Council to reduce the price of gas to 2s. per 1000 cubic feet; but only that day the Gas Committee had received a communication from one of the local associations saying “Don't lower the price of gas at all.” As the Corporation had to trade in both gas and water, they ought to make the two undertakings balance each other. The Corporation already charged an extra price to gas consumers outside the borough; and if the charge was lowered within the borough, he feared that the extra charge to outside consumers would have to be given up. People beyond the borough were supplied with Corporation water at less than cost price. Was the Corporation to give them also the advantage of having gas at a reduced price, and tax the residents in the borough to make up the deficiency so caused?

A vote of thanks was accorded to the retiring councillors, and the proceedings closed.

EDINBURGH AND LEITH GAS COMMISSION.

At their Meeting on Monday last week, a variety of questions engaged the attention of the Edinburgh and Leith Gas Commissioners. With respect to the petition of the *employees* at the Leith works to be put on the same footing as to wages as the Edinburgh workmen (see *ante*, p. 600), the Works Committee, to whom the matter was referred, reported that they had made a remit to the Engineers to report generally on the subject of hours and wages of the men. In connection with an application for a supply of gas to a mill at Colinton, it was estimated that the necessary piping would cost £1960. If the residents at Colinton undertook to use gas, it was suggested that the pipe should be laid at the Commissioners' expense; and the gas supplied at 4s. 2d. per 1000 cubic feet. It was reported that tenders had been entered into for the supply of coke at 6s. and 6s. 6d. a ton. It was agreed, on the recommendation of the Finance Committee, to pay the parliamentary expenses of the burgh of Leith (£1009) incurred in connection with the Gas Bill; also to settle with the Edinburgh and Leith Gas Company for the payment of stores (£23,000). Certain financial arrangements in connection with this matter were explained by the Clerk, who stated that the £28,000 of mortgages at 3½ per cent. asked for had all been subscribed. He also mentioned that he had written to the Leith Company, asking if they would accept payment in instalments, but they had declined. It was resolved that the system of book-keeping of the Edinburgh Company should be adopted, subject to such modifications as experience might suggest. Mr. Beveridge, it was reported, had decided that the Companies were entitled to interest on the price of their stores from Aug. 1. A statement from Messrs. Davidson and Syme was read concerning the final accounting with the Edinburgh Gaslight Company. One of the items referred to was a sum of £2163 14s. 6d., which represented deposits by consumers, some of which dated as far back as 1849. It was also mentioned that a sum of £635 for retorts was open to discussion. The documents, which were of a bulky nature, were sent to the Finance Committee. In regard to the account of the Parliamentary Agent for the Gas Bill (Mr. Beveridge), it was stated that this amounted to £4719 8s. 6d., of which he had been paid £3000 on account. It was agreed to pay a further £1000 on account; and to arrange for having the accounts taxed by the Auditor of the Court of Session. A communication was read from the burgh of Leith, asking that the supply of gas to the public lamps should be put on the same basis as in Edinburgh. The question was remitted to the Works Committee for consideration. A number of other matters of a routine nature were disposed of.

THE TESTING OF SWANSEA GAS.—At the meeting of the Swansea Town Council last Wednesday, the Town Clerk (Mr. J. Thomas) presented a report on the subject of the existing regulations in regard to the testing of Swansea gas. He pointed out that the only legal testing-place is at the works, and that any examination made elsewhere would be valueless in a Court of Law. At the same time he recommended the Council to consider the advisability of having their photometer put in proper order, and of appointing a duly-qualified examiner to make tests of the gas for the general satisfaction of the Corporation and consumers. The consideration of the matter was deferred for a month.

THE DINSMORE GAS PROCESS AT WIDNES.—At the last meeting of the Widnes Local Board, Mr. Gaskell, in moving the confirmation of the Gas Committee's minutes, remarked, in reference to the Dinsmore gas process, to which the Engineer (Mr. Isaac Carr) had alluded in his report, as mentioned in the *JOURNAL* last week, that the 13,000 cubic feet of gas per ton of coal which they were obtaining was produced with the use of only half their tar. If they could have used the whole of the tar, the quantity of gas might have been larger, and the quality better. In addition, the gas contained less sulphur compounds, other than sulphuretted hydrogen, than the ordinary gas, and was of a more permanent composition. He believed that such results as these had never before been attained in any gas-works on a manufacturing scale.

THE BIRMINGHAM GAS UNDERTAKING.

A VINDICATION OF THE CORPORATION MANAGEMENT.

An interesting pamphlet, constituting a retrospect and a vindication of the management of the gas undertaking by the Birmingham Town Council, has just been prepared by Mr. H. J. Manton, who, as a member of the Gas Committee and Works Sub-Committee, has had exceptionally favourable opportunities of making himself acquainted with the entire working of the concern. The history covers a period of twelve years; the purchase of the undertakings of the two Gas Companies having been completed on Dec. 31, 1875. A statement is given of the growth of the capital account, the separation of several outside districts, and the development and improvement of the works. Mr. Manton recalls the statement made by Mr. Joseph Chamberlain in March, 1874, of what would have been required to be spent by the old Companies for extension of works, and uses it as a basis of comparison with what has actually been done.

Mr. Chamberlain is reported to have said, "that the sale by the Staffordshire Company had increased during the previous ten years by 5 per cent. compound, and that of the Birmingham Company by 6 per cent. compound. Assuming 5 per cent. compound to be the average, the Companies would, in 14 years following, have had to raise, for extension of works to meet the demand, the sum of £1,000,000." During the period of Corporation management the alterations and extensions at the works have been very large. The Saltley works have been increased; and the Windsor Street station has been almost entirely reconstructed. The Fazeley Street station has been abandoned, and the site let. The Swan Village and Adderley Street works have been put into substantial repair. Considerable amounts have been written off for antiquated and abandoned plant. Neither of the larger works are complete; but as they at present stand in regard to producing power, the comparison with their daily capacity at the transfer is as follows, in millions of cubic feet:—Total capacity of the works in 1875, per day 15,047,000 cubic feet; total capacity of the works in December, 1887, 20,500,000 cubic feet; the completion of the purifying plant at Saltley, equal to retort and storage capacity, will add 1,500,000 cubic feet; and the filling up of the Windsor Street retorts, 4,050,000 cubic feet—making a total productive power of 26,050,000 cubic feet. The estimated capital expenditure required to provide for this increase during the next seven years is £45,000; a further estimated expenditure of £130,000 will complete the Windsor Street works, and bring up the total production per day to 32,500,000 cubic feet. Thus, for an actual net expenditure of £293,409, and an estimated expenditure for completion of £175,000—making a total of £468,409—the Gas Department will be enabled to meet the requirements of the next 12 or 15 years, at less than half the amount which was expected to have been spent up to the present date.

Passing next to the question of the gas sales, Mr. Manton states that the estimate was an increase of 5 per cent. compound per annum. The sale of gas in 1875 was 2327 millions. Over the same area as at the present time it was 2120 millions. The sale of gas in 1880 was 2676 millions. In 1887 it was 3378 millions, which is upwards of 4 per cent. per annum compound on the sale of 1875 over the same area. Thus it will be seen that while the estimate formed as to the increase of the public requirements for gas has not been quite realized, the corresponding outlay on capital account has been much less in proportion and the economic administration of the managers of the department verified.

Mr. Manton then goes on to speak of the charges for gas; and to compare them with those of other corporations and commercial companies; pointing out, as regards the former, that meter-rents are an item that is frequently overlooked in comparisons sometimes made to the disparagement of Birmingham, and that there are other local circumstances needing to be remembered before such comparisons are trustworthy. He shows that the difference between the highest price in 1875 under the Companies and that of 1888 under the Corporation is 11d. per 1000 cubic feet. The average difference is as follows:—1875, 3s. 1½d.; 1876, 2s. 10d.; 1880, 2s. 7½d.; 1888, 2s. 2½d. Thus it is apparent that the advantages gained by the public from the purchase of the gas undertaking have not been obtained by undue hardness of prices for gas, and may briefly be recited as follows:—Returned to consumers in the shape of reduction of prices from 1876 to 1880, on the basis of the prices of 1875, £210,000; reduction of prices from 1880 to 1887, on the basis of the prices of 1880, £365,000; contributions to rates and public purposes, £352,000—total, £927,000. As proving that this result has been obtained by efficiency and economy of administration, Mr. Manton quotes, from Field's "Analysis" for 1886, figures relating to the gas undertakings at Leicester and Nottingham. In the former town the manufacture of gas is carried on under the nearest conditions of similarity with Birmingham—little canal being used, the illuminating power being the same, the same proportionate capital invested, and the undertaking acknowledged to be well managed. Nottingham, however, differs from Birmingham in the use of 29 per cent. of canal, while the illuminating power of the gas is 1½ candles higher. The following are the figures cited, which show the cost per 1000 cubic feet of gas sold in the three places, namely:—

	Leicester.	Nottingham.	Birmingham.
Salaries and distribution wages	1.61d. ..	2.24d. ..	1.36d.
Total working expenses, including salaries, wages, and depreciation	11.36 ..	12.26 ..	11.59
Coals	5.46 ..	5.23 ..	5.22
Interest and sinking fund . .	8.65 ..	8.56 ..	7.29

Mr. Manton then goes on to vindicate the engineering and economic administration of the Gas Department, and sums up his case as follows:—"In concluding this survey of the financial and economical administration of the Birmingham gas undertaking, those now entrusted with its management readily bear testimony to the great ability which their predecessors brought to bear upon it, and the extent of the work done. The old Companies were about to launch out into extensive operations. The new managers were compelled at once to deal with the requirements of a rapidly-increasing town, to provide for an increase of producing power which should cover the probable wants of a generation. They were necessarily new to the work; and yet their successors are unable to point to errors of any magnitude, or expenditure on reckless experiment. The outlay they authorized has been made mainly on existing lines; and the departures therefrom, and from ordinary methods of production, have been chiefly in the direction of mechanical provision for the saving of labour and for the comfort of the employees—relieving them from that part of the carbonizing which is most physically trying to health and endurance. The table shows that there has been a substantial improvement in the quality of the gas over that supplied by the old Companies or stipulated by Parliament; and comparison of the cost of official supervision with other corporations and gas companies tells favourably for the Birmingham gas undertaking. Whatever success has been attained in approach to administrative completeness is due to the manner in which the Gas Committee have been served by its staff—the servants of the department—as well in the able reorganization of the office as in the conceptions of the Engineers. The employment of engineering experts would probably have increased the cost of plant; and the control of any Committee over the

outlay of such professional assistants would necessarily be less than its control over its servants. That the early managers were wise in their decision the event incontestably shows. It has been, both in Parliament and outside, a subject of discussion as to whether it is wise for the local authorities to supersede private associations in the supply of gas and water to the community. The opposition in respect of the supply of water being under public control has always been weaker than in respect of the supply of gas. At a very early date this was recognized by the House of Lords in the insertion of a clause in a Company's Bill obtained in 1854, giving power to the Corporation to buy the water undertaking within two years, and limiting the dividend upon new shares to a maximum of 6 per cent. The whole subsequent course of water legislation as affecting Birmingham, and the acquisition of the works, has had this basis—that the supply of water, being a sanitary necessity, the Sanitary Authority (having acquired the control), should not administer with a view to a profit; thus eliminating from the water undertaking the character of being a trade concern, which it possessed in the hands of a joint-stock Company. As to the gas supply, these conditions and limitations were wanting. The Corporation acquired no monopoly either of the supply of gas or of the method of lighting. Anyone can make for himself, if it pay to do so, or choose any other illuminant that pleases him. The manufacture is then conducted essentially on conditions such as existed under the Companies; and in no sense is it justifiable to regard the gas undertaking as a branch of the general corporate administration. That this was the light in which the Council of 1875 regarded the new property is clear from the manner in which they treated the new Committee, and the complete and entire confidence they reposed in it, by committing to it the delicate work of arbitration with outlying authorities in the event of any of them desiring to purchase the portion of the gas-works within their jurisdiction, and by bestowing on the Committee all the powers conferred upon the Council by the Gas Act of 1875—reporting from time to time thereon. This delegation was further important, inasmuch as it conferred on a Committee the control of a capital of more than two millions, and the exercise of a large patronage and influence, but accompanied by an immense responsibility, and demanding an arduous and disinterested devotion on the part of its members. To the responsibilities attaching to the conduct of a large trading concern have been added anxieties arising out of the connection with a Corporation which of necessity has been of a political character. In the hands of a representative authority, it may be difficult on all occasions to decide matters apart from the effect of such decision on political necessities; and to the usual arguments and conditions which would affect a rise or a fall of prices, have been added arguments as to the claims or otherwise which the common fund of the borough had upon the revenues arising out of gas manufacture. To steer a clear and a wise course when such occasions arise has been a task which would have taxed the ablest of administrators. Still it can justly be claimed that the revenues of the gas undertaking have relieved the strain on the borough fund, which has arisen out of a possibly too generous outlay in town improvements, maintained the efficiency of the works, observed a generous policy towards the officers of the staff, and provided for the comfort of the workpeople by lessening the demand on them for unremitting labour, and softening the most arduous conditions of their daily tasks, without putting a price on their commodity which was unjust to the customers of the concern."

THE PROPOSED AMALGAMATION OF MANCHESTER AND SALFORD.

In May last an Association was founded, under the presidency of Mr. Oliver Heywood, to consider the advisability of amalgamating the city of Manchester and the borough of Salford. About 1200 members enrolled themselves, and from them were formed two Executive Committees—one for the city and the other for the borough. These Committees presented their report at a meeting of the Association held on Monday last week. It was a document of considerable length, and dealt with the general question under the following heads:—The financial position, the sanitary condition, the commercial and industrial interests, and the moral and intellectual welfare of the community. As far as financial matters were concerned, the Committees had the assistance of Mr. Guthrie, the well-known Accountant of Manchester, who specially reported on the questions submitted to him for consideration. He divided his report into five parts. Part I. deals with the Manchester balance-sheet of 1886-7 and the Salford balance-sheet for the same period; setting forth the assets and liabilities of the respective Corporations. Part II. was devoted to the question of the rates, methods of assessment, and cost of administration. Part III. described the nature and probable cost of projected works, and their effects on the rates. Part IV. showed the effect of amalgamation on the separate interests of Salford, Broughton, and Pendleton. Part V. set forth the conclusions upon all the financial considerations involved in the amalgamation. According to the Manchester balance-sheet for 1886-7, the total assets were £9,409,387; the liabilities, £6,999,980. The surplus of assets over liabilities was therefore £2,409,407. The Salford balance-sheet for 1886-7 showed the total assets of the borough as a whole to be £1,748,983; the liabilities, £1,578,893—surplus of assets, £170,090. The excess of assets in the case of Manchester is about equal to the total rateable value for one year of all the property in the city; in other words, it amounts to 20s. in the pound. In the case of Salford, the excess of assets over liabilities is less than one-fourth of the total rateable value of the borough for one year (£750,678), or equal to 4s. 6½d. in the pound. The assets were, however, Mr. Guthrie ascertained, over-estimated to the extent of £241,067. Consequently, the total assets of the borough must be reduced by this amount. This changes the surplus of £170,090 into a deficit of £70,976. Instead, therefore, of there being a surplus equal to 4s. 6½d. in the pound on the rateable value of the borough, there is a deficit equal to 1s. 10½d. The Committee did not, however, deem it necessary to take into account this deficit in considering the effect of amalgamation. Such deficit might have some significance for Salford as a separate Corporation; but under amalgamation the joint city, Manchester and Salford, would still have a large surplus of assets over liabilities. Accepting the figures of the published accounts for 1886-7, the aggregate assets would be £11,158,370; the aggregate liabilities, £8,578,873—surplus, £2,579,497; or equal to 16s. 3½d. in the pound on the rateable value of the joint city. Thus the loss to Manchester on amalgamation on the capital account would be 3s. 8½d. in the pound, and the gain to Salford 11s. 9½d. in the pound.

In Part II. of Mr. Guthrie's report, the method by which the revenue of the city and borough is raised is disclosed. It is pointed out that the rates in both places are relieved by profits on the trading departments of the respective Corporations. It is remarked that when the profits are derived from trading outside the limits of the municipalities, a direct and unqualified relief to ratepayers is effected. When the trading is done within, the profits derived take the form of indirect taxation of ratepayers, and are equivalent to an addition to the rates. Thus gas and water might be supplied at actual cost price to the ratepayers; and in that case a levy of so much more in the pound would have to be made, sufficient to make

up the profit now obtained by trading. In Manchester, upwards of £70,818 profit was made in 1886-7 on various items—markets, tramways, gas, and miscellaneous—and applied in relief of the rates. This is equivalent to a rate of 7d. in the pound. Were it not for this profit, the rate levied would have been 3s. 9½d., instead of 3s. 2½d. The Gas Department shows a profit of £21,989—a comparatively small sum; but no charge is made by this department for the lighting of the street lamps, which costs £28,955. In Salford, trading profit, from like sources as those in Manchester, with the addition of £6036 from profit on water, amounted to £37,735. This is equivalent to a rate of 1s. 0½d. in the pound. Were it not for this profit, the average rates in Salford would have been 4s. 8½d. in the pound, instead of 3s. 8d. as levied. The Salford Gas Department charged £11,054 for lighting the street lamps; consequently her trading profits appear relatively larger than Manchester, where no charge was made in respect of this item. It is evident that high charges for gas and water may realize a profit to relieve the direct rates; but direct rates bring before ratepayers more clearly the cost of administration, and enable them to exercise more perfect control over the finances. The strict taxation of Manchester, *plus* trading profits and including redemption of capital, is 3s. 6½d. in the pound on the rateable value; and that of Salford, 4s. 7½d. by the last accounts. Amalgamated, the strict taxation would be 3s. 9½d. This is, however, subject to certain balances on revenue account; the Manchester city fund having an unexpended surplus of £20,046 2s. 7d., equal to 2d. in the pound on the rateable value, in relief of subsequent rates, while the borough of Salford and all its separate districts carry forward deficits to be made up out of future rates. The Manchester gas account exhibits a debit to profit and loss account amounting to £45,857 7s. 3d. (since reduced out of profits to £27,931 14s. 3d.), standing against a surplus and sinking fund of £740,007 10s. The water-works revenue account shows a deficit of £1393 9s. 8d. (since paid off). The Salford district water-works fund exhibits an old unappropriated surplus of £10,383 15s., accumulated prior to the passing of the Salford Improvement Act of 1870.

On the subject of the water supply, the Committees report that Manchester has provided the water supply for an extensive district, comprising altogether 36 townships, including those of the city and borough. The arrangement for a certain limited supply to a portion of Salford, one of the townships, called the Salford district, is a very liberal one; 1½ million gallons daily being supplied, at a sum equivalent to 2½d. per 1000 gallons, and an additional ½ million at 3d. per 1000 gallons. Broughton and Pendleton do not share in this excellent bargain (excepting a small portion of Broughton, formerly a part of Salford district). They derive water direct from Manchester, and are treated as out-townships; yielding a profit to the city on the water supplied to them. The net cost to Manchester of all the water consumed is 6½d. per 1000 gallons. In supplying 2 million gallons daily to the township called Salford district, Manchester loses about 3½d. per 1000 gallons. The Salford district in trading with this supply, which costs less than 3d. per 1000 gallons, makes a profit of £6036. For all excess above the 2 million gallons Salford has to pay 8d., or in some cases 9d. per 1000 gallons; but the Joint Legal Committee have reported that there is no legal obligation on the part of Manchester to supply any water to the Salford district beyond 2 million gallons per day, excepting for flushing sewers and cleansing streets. Consequently, Salford, unless she provides a water supply of her own, must ever be dependent on Manchester; and there is no legal limitation as to the price which Manchester may charge for water supplied for domestic or trading purposes in the Salford district, beyond the daily supply of 2 million gallons, which she already exceeds. In anticipation of the future development of the population of Manchester and Salford, a uniform rate for water becomes an important consideration for Salford. The Thirlmere scheme, when carried out, will place at the command of Manchester a practically unlimited supply of the best water in the country. Should Salford increase her industries and population, as well she may, the participation in an unlimited water supply at small cost becomes a factor of paramount importance, as an inducement for manufacturing to be established, by which the unoccupied and profitless land within the borough may be covered with rateable property. It would be incorrect to assume that Salford is secure from further anxiety as to water, while Manchester is incurring a large expenditure to provide for the future. If Salford is to acquire that prosperity which her position warrants, she should either endeavour to join Manchester and fully participate in the advantages of a perfect water supply at cost price, or she must run the risk of paying even more heavily in the future than she now does in Broughton and Pendleton for that element so essential to the promotion of manufactures, and absolutely necessary for the domestic comfort of her population. It is equally important that the gas supply should be uniform within one community like Manchester and Salford. At present, and for many years past, Manchester has enjoyed not only lower general rates, but a considerably lower gas-rate than Salford. The difference has been equivalent to a rate of 4½d. in the pound on the rateable value of the city, or an annual saving to the ratepayers of £43,594.

In considering the effects of amalgamation upon the separate interests of Salford district, Pendleton, and Broughton, treating the borough as a whole, it appears that they would be variously affected, but each would gain. The allocation of differences in all the rates, together with the assimilation of gas and water charges, would result under amalgamation in a net gain to the three districts on the rateable value as follows:—Salford district would gain in rates 4½d. in the pound; Broughton district would gain in rates 5½d. in the pound; Pendleton district would gain in rates 1s. 5½d. in the pound. Taking into account the increase of rates in 1887-8, and adding to Manchester and Salford respectively the cost of public works, the following prospective result is shown:—Manchester would lose on amalgamation 1d. in the pound; Salford borough as a whole would gain 3½d. in the pound; Salford district would gain 0½d. in the pound; Broughton would lose 0½d. in the pound; Pendleton would gain 1s. 1½d. in the pound. It must be noted, in connection with these figures, that Salford relieves the rates out of gas profits by a larger proportionate amount than Manchester. Taking into account the amount paid by the ratepayers by way of profits in the gas and other departments, and the amount of rates applied in the creation of permanent assets, the actual cost of administration at the present time, 1887-8 (with that year's additions to rates), would show an advantage on the side of Manchester of 10½d. over the borough of Salford as a whole; over the Salford district, of 1s.; over the Broughton district, of 0½d.; over the Pendleton district, of 1s. 2½d.

Viewing the financial question from every side, the Committees consider that there is no difficulty in amalgamating the city and borough. On capital account the united city would show a smaller excess of assets over liabilities than the city now possesses, owing to the Salford liabilities being actually greater than the assets. On the rating, Manchester would stand under somewhat less favourable conditions; and, including the cost of the projected sewage works, there would be a slight loss on amalgamation. Salford would have the advantage under amalgamation of lower rates than she has had to pay for many years past, with the additional benefit of cheaper gas. The only question, apparently, that can arise to

affect the rates adversely for Salford is the cost of the increased water supply for the district, under the Thirlmere scheme, with which Mr. Guthrie has dealt very fully in his report. This work, however, is as essential for Salford as for Manchester—more especially if the borough should extend industrially, as it is reasonable to hope, with ample water supply, she may. It is anticipated that the Thirlmere works will be completed in from three to four years. Interest upon expenditure in respect thereof will be added to the cost during the construction of the works; but redemption of loans must commence as from the 1st of January, 1891. It may be expected that towards these payments considerable contributions will be made out of trading profits, and by a decrease in the expenditure in connection with the Woodhead supply. Some increase in the revenue of the city, by an improved condition of trade, may also be looked for to afford additional means of meeting the expenditure. Should, however, these sources of income prove inadequate, the deficiency would have to be provided out of the city funds; and any additional rates for this purpose ought to fall upon the whole of the population, which on amalgamation would be entitled to enjoy the invaluable benefits of an unlimited supply of pure water. Were Manchester and Salford to unite in obtaining parliamentary sanction to the consolidation of the numerous redeemable loans they have incurred, and get an extension of time for the repayment of money spent in public works, there is no ground for expectation that the present generation will be burdened to any appreciable extent beyond the present rates. On the contrary, it may be anticipated that, with a moderate general increase in the prosperity of the trades for which the district is famous, the value of rateable property in a united city will be so enhanced that, were even a more liberal expenditure for the welfare of the citizens—and especially of the poorer classes—from time to time undertaken, even lower rates than the present might be found sufficient. It is difficult to represent in figures the actual economy which would result from single administration; but it is obvious that in all departments of the enlarged Municipality less expenditure would be incurred in administration than is at present required by the separate Municipalities. Hitherto the application to Parliament of one Corporation for increased powers has been watched or opposed by the other at considerable expense. Were the conflicting interests of the city and borough merged in the one object of promoting the welfare of the homogeneous population forming Manchester and Salford, parliamentary powers would be obtained more promptly and at less cost. Manchester may well covet the enhanced importance she would obtain by amalgamation with Salford. She would rank much higher as one of the largest cities in the empire, her commerce and industries would be represented to the world in greater magnitude than heretofore, and her facilities for more rapid growth in the future would be increased.

In the "Conclusions" to their report, the Committees say: "From the exhaustive inquiry which your Committees have pursued continuously during the last five months, there is but one conclusion possible—viz., that amalgamation of the city and borough will conduce to the welfare of the whole population, and ought forthwith to be carried into effect. The cost of administration will be reduced, or at least greater efficiency will be secured without higher expenditure than at present. Sanitary reform will be accelerated, and the opposition or indifference of divided authority removed. The commercial and industrial interests, instead of receiving partial attention as at present, will be considered as affecting the united population. The educational and intellectual institutions will become wider spread to embrace the large section of the population now disregarded in the many projects contemplated in the city for the benefit of the people. All remedial and ameliorative measures which the larger life and spirit of a great city promote will embrace Salford equally with the rest of the city. The policy of Manchester, in relation to questions affecting both communities, but, of vital importance to Salford, will cease to be exclusive; and the influence and financial power of the larger Corporation will be used to promote the common welfare of the whole of the inhabitants of Manchester and Salford. . . . The new Local Government Bill contains provisions for the union of two towns as one county, which meets the possible wishes of the inhabitants of Manchester and Salford; and your Committees earnestly hope such desire may be speedily expressed in favour of one government in the midst of a united people. A greater dignity and greater attraction will be offered to the cultured and experienced men of Manchester and Salford to enter the Corporation of the amalgamated towns with a view to making a great centre of northern commerce and industry the home of a well-employed, well-housed, and well-conditioned population. It remains now for the ratepayers of the city and borough to pronounce their decision, in order to effect without delay the amalgamation which your Committees unanimously recommend. There are no legal obstacles, no surrender of privileges, and, looking to the future, no material sacrifice of a financial character."

Two resolutions had been drafted for submission to the meeting. The first was—"That the report of the Joint Executive Committees now read be received, approved, and adopted." The second was—"That this Association, having carefully inquired into and considered the question in all its bearings, is of opinion that the amalgamation of Manchester and Salford will conduce to the general welfare of the inhabitants of the two towns, and that an Executive Committee be appointed to take forthwith such steps as they may deem necessary to carry out the recommendation for amalgamation contained in the report of the Association, and that they be instructed to represent the views of the Association to the respective Corporations to induce them to apply to the Local Government Board, or if necessary to Parliament, for powers to amalgamate the city and the borough." These were separately put to the meeting, and unanimously carried.

GAS LIGHTING IN THEATRES.—The stage of the Parc Theatre, Brussels, has recently been lighted by means of the Wenham "Safety" gas lamp; and we understand that the experiment is a complete success. This is an important move in the right direction, as the use of a number of naked lights over the stage is, as every one knows, a source of great danger; and seeing that the Wenham lamp is entirely enclosed, this risk is overcome. These lamps have also recently been used with great success at the Promenade Concerts at Covent Garden.

THE DARK STREETS OF LONDON.—At the meeting of the Bermondsey Vestry last Monday, the Chairman (the Rev. C. D. Lawrence) moved—"That the General Purposes Committee be instructed to bring up a report, as soon as possible, as to the lighting of the less frequented streets, alleys, and open places of the parish." He said he thought it was the duty of the Vestry, as the long winter evenings came on, to see to the efficient lighting of the public thoroughfares. The Chief Commissioner of Police had called attention to the lack of light in the streets in some districts; and the Vestry should act upon the hint given to improve it. To carry out a system of better lighting might involve additional labour and expense; but he was sure all would be willing to secure the safety of the district. He considered that local authorities could not spend too much money in ensuring an adequate supply of water, air, and light. After a discussion, the motion was adopted.

THE GAS-WORKS AT THE HANWELL SCHOOLS. SCHOOL MANAGERS AS GAS MAKERS.

For some time past the Managers of the Central London School District have been dissatisfied with the cost of manufacturing gas at their schools at Hanwell, which they consider excessive. A few weeks back they decided to call in Mr. W. F. Broadberry, of the New Southgate Gas-Works, to inspect their gas plant at Hanwell. A report has since been received from Mr. Broadberry; and it was brought up for consideration at the meeting of the Managers on Monday last week. The excessive cost, in Mr. Broadberry's opinion, was occasioned by the fact that the carbonizing arrangements at the works have been neglected. He found that there were four 5 ft. 6 in. retort arches, which were 8 ft. 6 in. long; these being set with 15-inch iron retorts, only 7 feet long, the make of gas from which was frequently less than 2000 feet per retort per 24 hours. He recommended that two of these arches should be provided with clay retorts—viz., four 16-inch circular retorts and one 20-inch by 14-inch oval retort, all 8 ft. 3 in. long. A setting of this description, he asserted, could be depended upon to make 17,000 cubic feet of gas per 24 hours, and also to produce from 9700 to 10,000 cubic feet per ton of coal carbonized, as against 7985 feet, which appeared from the accounts to have been the average quantity obtained per ton during the last two years. The average amount of gas now made per annum was 4,277,000 cubic feet, and to produce this 535½ tons of coal were carbonized. With the suggested improved setting, he calculated that there would be an immediate saving of 100 tons of coal per annum. He also recommended that screened Silkestone gas coal from South Yorkshire should be used, instead of the Durham unscreened he saw at the works. The former, he remarked, was a preferable coal; and taking into consideration the locality of the works, it should be obtained at about 9d. per ton cheaper. He urged that attention should be at once given to various valves about the works, which were set fast. With regard to the tar yielded by the coal carbonized, the accounts indicated that only 7 gallons per ton had been obtained, while the amount should have been 12 gallons with the low heats employed; the remainder having been presumably lost through the store-tank being unsound. With the setting recommended, the unsaleable tar could be burned under the retorts in lieu of coke, and the coke so saved used at the schools, and credited to the gas-works. He saw no reason why gas should not be manufactured at the holders for 2s. 7d. per 1000 cubic feet. In the course of the discussion which followed the reading of the report, it was stated that a supply of gas for the schools could be procured at a cheaper rate from the Brentford Gas Company; and one member incidentally mentioned that the gas during the last twelve months had cost them 4s. 10d. per 1000 cubic feet to manufacture. The report was subsequently referred to the Farm Committee for consideration.

THE RENEWAL OF THE LONDON COAL AND WINE DUTIES.

At the Meeting of the Metropolitan Board last Friday—the Right Hon. Lord MAGHERAMORNE in the chair—the Works Committee presented the following report:—"Your Committee have to report that, in pursuance of the reference made to them by the Board on the 28th of September, a Sub-Committee have had an interview with the Coal and Corn Finance Committee of the Corporation of London on the subject of the coal and wine duties. The Corporation Committee stated that their object in seeking the interview was to ascertain whether the Board would, as it had done in previous years, join the Corporation in giving notice of a Bill to be introduced into Parliament next year, providing for a renewal of the duties. It appears to your Committee desirable, for the following reasons, that the Board should co-operate with the Corporation. It is believed that the majority of the inhabitants of the Metropolis would look with favour upon a renewal of the duties. In January next the inhabitants will be called upon to elect the persons who are to compose the new County Council of London; and it is right that the Council, the members of which will thus be directly elected by the ratepayers, and will presumably be in a position to know and express the ratepayers' views, should have an opportunity of deciding whether it is expedient that the coal and wine duties should be renewed. When Lord Randolph Churchill, speaking as Chancellor of the Exchequer in November, 1888, to the Board and the Corporation, stated that the Government were not prepared to assist the two bodies in obtaining a further continuation of the duties, he intimated that, if it were made clear that a large majority of the inhabitants of London desired that the duties should be continued, this circumstance might lead the Government to modify its decision. If, therefore, the new County Council, coming fresh from the ratepayers, takes the same view as that taken by the Board and the Corporation, it is quite possible that the Government may modify its previously expressed opinion, and may be induced to support the Metropolitan authorities in asking Parliament to consent to the duties being renewed. The Board, therefore, in giving notice jointly with the Corporation of the intention to introduce the Bill, will only be preparing the way for such subsequent action as the County Council, when it comes into office, may determine to take. Your Committee accordingly recommend that the Board do join the Corporation in giving notice of the intention to introduce a Bill for the renewal of the coal and wine duties."

Mr. E. R. COOK, in moving the adoption of the report, pointed out that the Board now stood in a position, as regarded the introduction of Bills into Parliament, totally different from that which it had ever before occupied, inasmuch as they would be acting for a body which was to succeed them. It seemed to him that the Board should be rather liberal in the way of giving notices of Bills; and thus show that they had a desire to hand over the affairs of the Metropolis to the new body in as good a working order as possible. With reference to the coal and wine duties, this was not a question of public improvement, but of public policy. The present Government, through Lord Randolph Churchill, had said that on this question the people of London would have an opportunity of expressing an opinion about it, which they could do through the new body. If, in the opinion of the new Council, it was suggested that the coal duties should be renewed, he had little doubt that the Government would agree thereto.

Mr. EDWARDS questioned the advisability of going on with the matter, in view of the fact that two successive Governments had decided against the duties.

Mr. RICHARDSON said it had been stated that the country would receive, under the new Local Government Act, an addition of from two to three millions of money to their funds. If this were so, the ratepayers would have a *quid pro quo* for the loss of the coal and wine duties. It therefore seemed to him somewhat strange for the members of the Board to put their names on such a Bill as was proposed, before making inquiry as to whether or not it was a fact that the country would receive the additional amount mentioned.

Mr. RUNTZ was doubtful if any such benefit would be derived as had been mentioned by Mr. Richardson, because of the onerous character of the new obligations imposed by the statute in question. He was of opinion that the Board should afford the new Council, which would be a directly representative body, an opportunity of bringing the matter forward by giving notice of the Bill.

Mr. MARK H. JUDGE moved, as an amendment—"That, under present circumstances, the City Corporation be informed that the Board cannot join them in giving notice of a Bill in Parliament for the renewal of the coal and wine duties."

Mr. PURDY seconded the amendment.

The CHAIRMAN, however, ruled the amendment out of order, as being a direct negative to the motion.

Mr. COOK hoped that the Board would continue the policy it had adopted on this question for some years past. He said there were 160 towns in England having coal dues, mostly for the improvement of harbours and other matters connected with commerce; and he maintained that the Metropolis ought to have the dues for effecting street and open space improvements.

The report was approved by 29 votes to 5.

THE VALUE OF GAS SECURITIES.

[From *Money*, Oct. 17.]

In view of the vicissitudes which gas stocks have undergone during the past ten years, it is interesting to take a retrospect, especially when the present value is borne in mind. *Money* has so consistently championed the cause of gas, in spite of innumerable obstacles, that it is no way surprising that we from time to time receive letters couched in appreciative terms, and acknowledging our steadfast adherence to the immutable virtues and merits of gas as the illuminant *par excellence*. The following is a sample of many communications from grateful shareholders who have been induced by our advice in the past not to part with their gas holdings:—

To the Editor of "Money."

Sir,—On the 8th of October, 1878, there appeared in *The Times* a telegram from America, stating that Mr. Edison had just solved the problem of the electric light, and could divide it to any extent. This telegram was used by the promoters of electric light companies to its full extent; and numbers of holders of gas stocks took fright, and threw their property on the market—causing a panic which lasted for a considerable period. A decade has passed away; and during that time gas has had a regular and steady increase of prosperity. The prices of the Metropolitan Companies' stocks have risen fully 100 per cent. This must be very gratifying to you, who from the first have used your utmost endeavours to prevent holders from parting with a valuable security; and I am sure the best thanks of those who did not sell in a fright are due to you, and from no one more so than the writer, who was then, and is still,

A SHAREHOLDER IN EIGHT GAS COMPANIES.

Oct. 8, 1888.

Before the date mentioned by our correspondent, there were already vague rumours floating about as to the coming revolution to be effected by the introduction of the electric light; and the "bears" of gas stocks were at work endeavouring to depress the price of the securities. In September, 1878, the quotation of The Gaslight and Coke Company's "A" stock fluctuated between 168 and 183. In October of that year, owing to the telegram alluded to by our correspondent, the price of this stock sank as low as 140; while the highest quotation for the month was only 173. Owing to the success which attended the "bear" tactics the range of prices in 1879 averaged 155½. And so the game went on for a year or two; the "bears" doing all they could, upon one pretence or another—their bogey, which they trotted out persistently, always being the electric light—to depreciate the market value of gas stocks.

It was not until 1881 that anything very decided was done, calculated to give even a colourable pretext to the croakings that the enemies of gas had for so long indulged in. In the issue of *Money* of the 6th of April, 1881, there appeared an article entitled "The Electric Light Scare Again," in which we observed that "within the last few weeks the gas stock 'bears' have once more trotted out their turnip-headed ghost to alarm feeble folk, and make them believe that the end of the gas world had at length arrived." We then showed how the bears were discomfited and utterly routed, and how amusing it was to watch the "wily jobber cunningly endeavouring to persuade the broker that he could only take his client's stock for the account as a favour, the next day exhibiting his poverty of stock by asking the broker if he would like to deliver for cash; thus showing he had other engagements he could not meet." Our advice then, as it has ever been since, was to strongly urge gas shareholders not to be scared into parting with their securities. What was the result? In our issue of the following week, April 20, 1881, we wrote as follows: "On Tuesday, the 12th inst., The Gaslight Company's shares were quoted 175½-176 in the Official List, a rise of 5 from the artificial price to which they had been knocked down by the 'bears' within the previous few days. But there came a day of reckoning for these gentlemen; and it happened to be on the very next day, which was the settling-day on the Stock Exchange, and the state of affairs was speedily disclosed by a rise on that morning to 179½-180, notwithstanding the recent glorification of the electric light." Those were the days of the electric light scare. To-day the holders of gas stocks are wiser; and the present price is now 250—thus endorsing our correspondent's opinion—that during the past decade there has been an appreciation in the value of these stocks of 100 per cent.

THE ELECTRIC LIGHTING EXPERIMENT AT BARNET.

THE CONTRACTORS ON THEIR DEFENCE.

In the *JOURNAL* last week (p. 690) we made reference to the experiment in electric lighting which is now being carried on at Barnet, and reproduced, from a local paper, a comparative statement of the promises and performances of the contractors, as drawn up by a resident. Our readers will recollect that the latter fell far short of the former. The contractors (Messrs. H. F. Joel and Co.) have since sent to the *Electrical Review* what may be regarded as their "statement of defence;" and we therefore accord to those portions of it bearing directly upon the lighting arrangements the same publicity that we gave to the charges made against them. Messrs. Joel and Co. say: "This [Barnet] is the first installation of town lighting by incandescence lamps in series, and we had enormous difficulties in obtaining the novel fittings in the short time at our disposal. Our contract was not signed until July 6. We did not obtain the official plan showing the position and number of the lamps until some time after, and we found that we had to fit up 71 street lamp-posts, five miles of overhead wires, nearly one mile of underground wire, dynamo, engines, &c., in about five weeks. We asked the Local Board for six months in which to do the work permanently. This they were unable to grant, as the Gas Company's contract expired at the end of August, and we had to light up on the 1st of September. Under such circumstances, we were compelled to use temporary appliances, which we are now replacing by permanent plant, and we expect shortly to have our duplicate sets of engines, dynamos, &c., in proper working order. Our contract is for 71 32 candle-power lamps, but we have substituted many 50 candle-power lamps in the High Street, &c., in order to make a good display; and the opinion of competent and unbiased persons is that the light is a success, and we are much gratified at the orders we have received for private lighting, and the general good feeling shown towards us by the townspeople of Barnet."

The South Barracas (Argentine) Gas Company was registered recently with a capital of £100,000, in £10 shares.

LINES TO THE ELECTRIC LIGHT AT THE GREAT WESTERN RAILWAY TERMINUS.

BY A MISANTHROPIC GAS-HOLDER.

[From the *St. James's Gazette*.]

Twinkle, twinkle, little Arc—
Sickly, blue, uncertain spark;
Up above my head you swing,
Ugly, strange, expensive thing!

Now the flaring gas is gone
From the realms of Paddington,
You must show your quivering
light—
Twinkle, blinkle, left and right.

When across the foggy air
Streams the lightning's purple
glare,
Does the traveller in the dark
Bless your radiance, little Arc?

When you fade with modest
blush, (rush,
Scarce more bright than farthing

Would he know which way to go,
If you always twinkled so?

Cold, unlovely, blinding star,
I've no notion what you are,
How your wondrous "system"
works,
Who controls its jumps and
jerks.

Yours a lustre like the day!
Ghastly, green, inconstant ray!
No; where'er they worship you,
All the world is black or blue.

Though your light perchance
surpass
Homely oil or vulgar gas,
Still (I close with this remark)
I detest you, little Arc!

METROPOLIS WATER SUPPLY.

According to the returns furnished to the Registrar-General by the London Water Companies, the average quantity of water supplied daily to the Metropolis during the past month was 168,890,449 gallons, against 165,182,640 gallons in the corresponding month of 1887. The number of houses served last month was 742,869, or 227 gallons per house, and 29.1 gallons per head of the population. In August, 1887, the number of houses supplied was 730,258; and the quantity of water allowed for each person, 29 gallons. Of the entire bulk of water supplied last month, 83,491,556 gallons were drawn from the Thames, and 85,398,893 gallons from the Lea and other sources.

In his report to the Registrar-General on the quality of the Metropolitan water supply last month, Dr. E. Frankland makes the following remarks:—"Taking the average amount of organic impurity contained in a given volume of the Kent Company's water during the nine years ending December, 1876, as unity, the proportional amount contained in an equal volume of water supplied by each of the Metropolitan Water Companies and by the Tottenham Local Board of Health, was:—Kent, 0.6; New River, 0.9; Colne Valley, 1.3; Grand Junction, 1.3; Chelsea, 1.4; Tottenham, 1.4; West Middlesex, 1.6; Lambeth, 1.6; Southwark, 2.2; East London, 2.4. The Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies contained in every case less organic matter than the August samples; the proportion present being exceptionally small for river water. All the samples were clear and bright. The water principally derived from the Lea, and distributed by the New River Company contained even less organic matter than any of the Thames waters; whilst the proportion of organic matter in the East London Company's supply, although small in absolute amount, was slightly greater than that in the Thames-derived waters. Both samples were clear and bright. The deep-well waters of the Kent and Colne Valley Companies and of the Tottenham Local Board of Health contained, as usual, only a very small quantity of organic matter. The Colne Valley Company's water was not softened to quite the usual extent."

In the course of their report to the Official Water Examiner for the Metropolis (General A. De Courcy Scott, R.A.) on the composition and quality of daily samples of water supplied to London last month, Messrs. Crookes, Odling, and Tidy say: "The analyses of the waters of the past month show them to have been of high quality; a manifest reduction in the dissolved organic matter being apparent. Thus, during August, the average oxygen required per gallon for the Thames-derived waters, when examined by the oxygen process, was 0.071 grain, whilst for September it was 0.043 grain. In like manner the organic carbon shows a reduction from 0.120 grain per gallon in August to 0.104 grain in September. The unusual meteorology of the summer, referred to in a previous report, has had its influence (as we should have expected) on the character of the waters. They have, however, throughout been of excellent quality. Of 175 samples examined during September, 165 were found to be absolutely free from any trace of visible suspended matter."

BRADFORD CORPORATION WATER SUPPLY.

THE FUTURE SOURCES OF SUPPLY.

In the course of a lecture delivered at Bradford, on Monday evening last week, by Mr. R. Shackleton, on "The Past, Present, and Future of the Bradford Water Supply," he said, with regard to the first part of his subject, that he had nothing but admiration for the Bradford Town Council of 1854. At that time bad trade prevailed in the district and the country; but the Council had the courage to enter into negotiations which laid a good foundation for the future with regard to water-works. From 1854 to 1874, £1,000,000 was spent; and the result was that 7½ million gallons of water per day were obtained—the cost being 4d. per 1000 gallons. This was a splendid step in the right direction; and it formed a foundation upon which a system could have been built in order that the water-rates might be kept down. But from 1875 to 1877 this state of things was changed, and the price of water was increased to 14½d. per 1000 gallons. He asked if this did not show that something was very seriously wrong, and that money had been thrown away almost in cartloads. He thought it would not need much to convince anyone that some very serious blunder had been committed. The lecturer proceeded to quote statistics relating to the quality of water consumed daily by some of the large manufacturing firms in Bradford, with a view of showing that the industries of the borough had been heavily handicapped, and that the rates had been increased, by reason of the expenditure on the water-works. He pointed out that owners of cottage houses paid a water-rate equal to about 18d. in the pound; and that the occupiers of warehouses paid rates varying from about 18d. to 3d. in the pound, under certain modifications. He was in Glasgow the previous week, and found that the water-rate was only about 1d. in the pound. This seemed to him to be a very serious difference. He did not like to "cry over spilled milk," but he was of opinion that a lesson ought to be learned from the blunders of the past, and that an attempt should be made to do better. With regard to the future supply, the only schemes that held the field were the Grimwith and the Nidd. He explained the first scheme of the Water-Works Engineer (Mr. A. R. Binnie, M. Inst. C.E.) with regard to the Nidd. The cost of this scheme was £876,000, and for this there would be 5 million gallons of water per day. The increase in the consumption in the borough was at the rate of 200,000 gallons per day from the 1st of January in each year. The interest on the money expended and the sinking fund, at 4½ per cent., was £35,478. A deficiency would thus be made which would require a rate of 9d. in the pound for the first year, 8d. for the third year, 7d. for the fifth

year, and 4d. for the tenth year. Mr. Binnie's Grimwith scheme would cost £523,000; the quantity of water given being 4½ million gallons per day. The amount of interest on the expenditure and the sinking fund was £23,535. To pay off the money it would require a rate of 6d. in the pound for the first year, 5d. for the third year, 4d. for the fifth year, and 1d. for the tenth year; to which sum must be added the manorial or unexhausted mineral rights. Mr. Binnie put down at £188,000 the cost of the new conduit at Grimwith. From this sum he (Mr. Shackleton) contended that £141,000 ought to be deducted as unnecessary expenditure. A further sum of £120,000 should be taken off the original amount of £523,000; thus making a total of £260,000 that ought to be deducted. This sum of £260,000 would give a rate of 2½d. in the pound in the first year, of 1½d. in the third year, and of ¾d. in the fifth year. In the tenth year there would be a profit of about £790,000. All these calculations were based upon the assumption that water cost 6½d. per 1000 gallons. Referring to a visit recently paid to the Nidd district, he said they obtained a sample of quite clear water from the river; but three hours later a sample which was more like ink than water was drawn from the same place. This change had been brought about by rain. The Nidd scheme was therefore a dangerous one; and without hesitation, he called the Grimwith scheme the best for Bradford for the present. He wanted to secure, with respect to the water supply, both quantity and quality, and the expenditure of as small a sum of money as possible until the revenue increased. After the Grimwith scheme was exhausted, he would draw upon the waters of the Nidd, and store them.

STOCKTON AND MIDDLESBROUGH CORPORATIONS' WATER SUPPLY.

At the Meeting of the Stockton and Middlesbrough Water Board on Monday last week—Mr. Alderman T. Hugh Bell in the chair—a discussion took place on a suggestion made by Mr. J. Mansergh, the Water Engineer, that the Board should proceed with the construction of the Blackton reservoir. Alderman Bulmer expressed some doubt as to the desirability of doing anything at Blackton just yet. He said they were at present not taking more than 62 million gallons of water a week to the two towns; and they would thus have a large margin after the Hury reservoir was completed. They would then have a storage of 300 million gallons; and after allowing 22 millions a week for compensation, they would have left 21 million gallons to add to the 60 millions they were pumping at Broken Scar, or a total weekly supply of 81 million gallons, so that in a dry season they could keep a store for 140 to 150 days' supply. He thought, moreover, that they were making a gross mistake in constructing the Blackton reservoir; and he did not see that they were at all justified in spending any more money, because in his opinion there would not be sufficient water to fill the two reservoirs—not more than would keep the Hury reservoir full. They were simply killing the district by the capital they were spending. He thought they might allow the matter to rest for the next ten years; and as soon as the time arrived when their supply was insufficient, they could draw from a mill dam across the Lune at flood time, where they would not be called upon to give compensation. The General Manager (Mr. D. D. Wilson) said the estimated cost of the Blackton reservoir was £75,000. As to the estimated requirements of the district in the near future, Mr. Wilson stated that during the last 18 weeks the pumping varied from 48 million to 65 million gallons weekly; the average being 59½ million gallons. In 1868 the weekly supply of water for manufacturing purposes was 12,443,000 gallons, whereas in 1878 it was upwards of 28,261,000 gallons; being an increase in the ten years of 15,000,000 gallons. During the present year he estimated that the average weekly consumption of water for manufacturing purposes would be about 43 million gallons. The completion of the Hury reservoir would give an increased supply of about 15 million gallons per week; but when the Sadberge reservoir was finished, the districts at present insufficiently supplied would absorb 3 million gallons per week, and reduce the available margin to 12 millions. So that if the demand for manufacturing purposes increased at the rate of 1,500,000 gallons a year, and for domestic purposes at the rate of 500,000 gallons, the whole of the extra supply provided by the Hury reservoir would be exhausted in six years; and during the latter part of this time, the Board would be in the same position with regard to penalties that it was in before. The Chairman pointed out that the increase during the ten years between 1868 and 1878—a period of great development—was no greater than the increase in the ten succeeding years, which was a period of depression. So that, in spite of the depression in trade, there had been a great increase in the water consumption of the district; and thus, even if trade were as bad in the future as it had been in the past, they would have to expect an increase during ten years of between 14 and 15 million gallons. Alderman Fidler asked if there was anything in what Alderman Bulmer had said about the Hury reservoir absorbing the water from the whole of the watershed of the district. The Chairman replied that the question had been put on many occasions, and had been answered by Mr. Mansergh and others. There would come down the valley in one night as much water as would fill the reservoir three or four times over. Mr. Wilson said four inches of rainfall would suffice to fill it. The Chairman then asked whether the Board intended to go on with the Blackton reservoir or not. If they decided upon going on, they could either commence in such a way as would only commit them to the expenditure of £10,000, or they could resolve at once to proceed with the expenditure of the whole amount. He moved—"That Mr. Mansergh be instructed to prepare plans and specifications for the construction of the Blackton reservoir and the low dam, and to make any investigations, either by trial-holes, bore-holes, or otherwise, which he may think advisable to enable him to do so." Alderman Bulmer moved, as an amendment, that they should first instruct Mr. Mansergh to report as to what loss of water there would be in the Blackton reservoir if they moved the bank to the high-water mark of the Hury reservoir. He thought that if the loss was only small, it would be policy to allow four or five years to elapse before they spent any more money. They were killing the district with the capital account; and if they went on as they had been doing, there would never be a dividend from the water undertaking, but the ratepayers would always be called upon to subsidize the works to meet the payments for interest and redemption. After some discussion, the motion was carried Alderman Bulmer being the only dissident.

THE WINDSOR AND ETON WATER-WORKS.—The Town Clerk of Windsor (Mr. G. H. Long) has lately received the award of Mr. R. C. Driver, the Umpire appointed to adjudicate in an arbitration between the Corporation of Windsor and the Trustees under the marriage settlement of Mr. W. H. Cutler, the previous owner of the water-works, as to the sum to be paid by the former for the Tangier mill, house, stores, and land, with bridges and roads, appurtenant to the works they have lately acquired, and a necessary portion of them. The amount claimed by the Trustees was £9000; one item being £350 for compulsory sale. The Umpire has awarded £3200—a difference of £5800; and as there can be no appeal, this sum will have to be accepted.

NOTES FROM SCOTLAND.

(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, *Saturday*.

The work of transferring the Edinburgh and Leith gas undertakings to the Corporations has, in the matter of details, proved to be a more onerous task than anyone unacquainted with the business could ever have dreamt it would be. Some of the officials have been toiling in the preparation of statements for the Commissioners, or arranging under their different heads the funds of their old employers, the Companies, to the extent of twelve, and sometimes even sixteen hours a day—a wearisome task, for the performance of which it is to be hoped both the Companies and the Commissioners will remember their hard-worked servants. While this is true of the officials, it is also the case that the Commissioners have not been idle. Besides frequent Committee meetings, there have been many public meetings, at which an astonishing number of items of business have cropped up. A meeting of this nature was held on Monday last; and another is to be held on Monday next. At Monday's meeting (as will be seen by the report given elsewhere) the subjects dealt with ranged over a wide field. When one considers how often the Commissioners have of late gone through similarly long *agendas*, and how often they will require to struggle through others during the next few months, it will be seen that, in the meantime at least, the lot of the Gas Commissioner here is not a "happy one." It is a satisfaction, however, to be able to state that the business of the Commission is being very efficiently carried on. For this, no doubt, the chief credit lies with the officials, who are an exceedingly painstaking body; but it is also true that the Commissioners are, on the whole, sensible and moderate.

As I mentioned last week, the recent gas transfer in Edinburgh is frequently mentioned at public meetings in connection with the current municipal elections. One of these is worthy of notice. Mr. Pollard, C.A., one of the most active of the Gas Commissioners, informed the electors of the Calton Ward on Monday night that the Commissioners had secured a contract for 120,000 tons of coal for the present year at from 3s. to 3s. 7d. per ton cheaper than last year, by which a saving of £22,000 would be effected. Whether it was judicious to mention this circumstance is open to question, because its effect will probably be to lead to a clamour for a reduction in the price of gas, with which, on account of the heavy charges upon the Commissioners this year, they may be unable to comply.

One of those periodic discoveries of "mares' nests" which are so common in the many-sided questions of gas supply, has taken place at Dundee. Like most other instances, this one takes its rise in "bad gas." The complaint, ventilated by means of newspaper correspondence, is that air is mixed with the gas as it leaves the retort, and that, inferentially, the community are charged at the rate of 8s. 8d. per 1000 cubic feet for atmospheric air. The first writer wanted information on the subject; the second, whether in league with him or not it is impossible to say, was able to give it, stating that the air was "sucked in through a 3-inch pipe, or through a pretty large meter." This writer suggested that the gas should be tested in the interests of the public, and urged a public inquiry into "the whole affairs of these gas-works." The newspapers state in a foot-note to this letter that, on inquiry, they have ascertained it to be the case that air is mixed with the gas, in conformity with the practice of the most eminent gas engineers, and that the effect is not to diminish the lighting power of the gas, but to facilitate its purification. Thereupon the Editor of one paper gives vent to the desire that the process should be fully and frankly explained; and the scientific authority for adopting it stated. With this he couples the sapient remark that "consumers are naturally prejudiced in favour of gas undiluted with air, as they are in favour of milk undiluted with water." The Dundee Gas Acts require the Commissioners to furnish gas of 18-candle power; and the monthly statistics issued show it to be frequently over 27, and never under 26 candle power. With gas of this quality supplied, and no harmful effects averred, it is difficult to see where any ground of complaint comes in.

The village of Cowdenbeath, in Fifeshire, was on Tuesday night lighted for the first time with oil gas. The plant has been fitted up by the Glasgow Patent Paraffin Gaslight Company. In this instance coal gas has not been superseded; the place having formerly been without a gas supply. Two retorts capable of producing 300 cubic feet of gas per hour have been erected; and provision has been made for extending the works. The gas is to be charged for at the rate of 5s. per 1000 cubic feet.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, *Saturday*.

Gas affairs have been prominently dealt with this week at meetings of the Greenock electors with their representatives in the Town Council. At the meeting of the Fourth Ward ratepayers on Thursday night, Bailie Shearer, Vice-Convenor of the Corporation Gas Committee, remarked that the Gas Trust was in a flourishing condition, and that the revenue from all sources last year amounted to £36,661 4s. 9d.; being an increase on that of the previous year to the extent of £453 17s., and leaving a net profit to the general purposes of the Police Board of £3000, or £500 in excess of the sums set apart for a similar charge for the last two years. The works and all the appliances connected therewith had, he said, been maintained in a very efficient state; and it was gratifying to him to be able to state that the Klönne bench of retorts, erected in 1884, at a cost of £4763, continued to work admirably, and that the debt incurred in its construction had been wiped off from revenue since then, with the exception of £1078 18s. 6d., and which he thought they would be able to pay off this year. The financial position of the Trust at the close of the year appeared so satisfactory that, in view of the increasing consumption of gas, which they wish to develop as far as possible, the Gas Committee considered that there was an opportunity for making a reduction in the price, and accordingly they resolved upon charging 3s. 6½d. per 1000 cubic feet for the current year, or a reduction of 2½d. per 1000 feet. Hitherto the reductions had been made by 5d. at a time; but it was considered safer to adopt the 2½d. reduction on this occasion, and concede a similar amount again next year if the revenue would permit. Mr. Cameron, speaking at the same meeting, said that he could not help thinking that £3000 was too large a sum to take out of the pockets of the gas consumers and pay into the town's coffers. He held it to be not only unfair, but opposed to the interests of the town, to make a profit upon the gas-works. Last year, for instance, the gas consumers paid about 2d. or 3d. per £1 of the town's taxes; and he for one obtained the benefit of this, as, comparatively speaking, he burned little or no gas in Greenock. A great many persons were in the same position as himself, either because they lived out of the town or preferred to burn oil; but he was sure that neither he nor those situated like him wished to keep down the taxes at the expense of the gas consumers.

Ex-Bailie Ure, speaking of the Glasgow gas supply undertaking to his constituents on Thursday night, expressed the hope that the price of Glasgow gas would undergo a further reduction next year. At present, he said, the price was 2s. 8d. per 1000 cubic feet; whereas when he entered the Town Council the price was 5s. per 1000 cubic feet. He also mentioned

that there were now in use in Glasgow 11,000 gas stoves, cookers, and heaters which had been supplied by the Gas Trust; and there were likewise in use 537 gas-engines within the area of the gas supply. He considered these facts to be very important; for when there was little to do, in the way of providing gas for illuminating power in the summer time for the citizens, they had to supply a large quantity for these gas-stoves, &c.

Mr. Mechan, addressing his constituents of the Thirteenth Ward on the same evening, also referred to the business of the Gas Trust. He remarked that the Gas Committee were hopeful that they would be able to reduce the price of gas next year. In regard to the complaints that were made as to the quality of the gas, he thought these arose from the manner in which the gas was consumed; and he suggested that the Gas Committee might supply gas-burners free to the consumers, and that men should go about, and fix burners suitable to the pressure in different localities.

The new gasholder at the Rothesay Gas-Works was put into operation for the first time on Thursday afternoon. Provost Thomson performed the ceremony of turning on the gas; and the holder gradually rose, until it was about half full, when the gas was turned off again. The working capacity of the holder is 72,000 cubic feet; and it has been erected on the site of a smaller one, which was only capable of storing 10,000 feet. The new holder works in a cast-iron tank 51 ft. 6 in. diameter by 20 feet deep, and is in two lifts, the outer one being 50 feet, and the inner one 48 ft. 6 in. in diameter. The contractors were Messrs. Hanna, Donald, and Wilson, of Paisley, who have carried out the work in a most satisfactory manner. The contract price was £1560; and with a few extras the total cost will be about £1500. Rothesay has now a gasholder capacity of about 128,000 feet, which is nearly double what it was before, and is sufficient to meet any increased requirements for years to come.

On Thursday last 396 shares in the Falkirk Joint-Stock Gas Company were sold by auction, and realized from £2 8s. to £2 13s. per share.

The upward movement in the price of sulphate of ammonia continues. A contract has been made this week for 350 tons at £12 per ton, October to April delivery. The spot price is steady at £11 15s.

A certain degree of firmness has been shown in the pig-iron market this week; and the prices are advanced generally about 1s. per ton over the closing prices at the end of last week.

The coal market has shown considerable activity during the week, prices being firmer in almost every instance, and the wages of the miners are being systematically advanced throughout a large portion of Lanarkshire.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Oct. 20.

Sulphate of Ammonia.—The market is undoubtedly stronger; and the unforeseen continuance of the demand, at present extending far beyond the accustomed period, must be as highly gratifying to the producers as it will be discomfiting to such consumers as have been delaying purchases in anticipation of lower values during the slack months—October and November, according to theory, being considered as such. The large French requirements (which do not appear to be yet quite completed) clearly prove that the abstinence of these consumers during the earlier months and the summer of this year was simply a matter of using up every available ounce of stock and home produce, and not, as many would have it, a change of front—i.e., a transfer of favour from sulphate to nitrate. Germany, moreover, seems to recognize the position; but as many consumers there have been earlier in the field, they display less anxiety, and at present buy only parcels as actually required for present and near delivery. What strengthens the market particularly at the moment is that the liquor supply is by no means so prolific as it has been in past years at this particular season. This may be attributed to the generally bright weather experienced during October; and while the production remains behind the spot demand, prices in their natural course are not likely to slacken. Further, there is the tone of the nitrate market, repeatedly referred to, and which indicates a probability of further enhanced prices. To-day's quotations of October-November cargoes are now very close upon 10s. per cwt.; but the actual shipments during October and November will naturally regulate values more than the sentiments expressed by sellers at present. The closing values of sulphate may be called £11 12s. 6d. to £11 15s. at all ports.

LONDON, Oct. 20.

Tar Products.—Benzols continue neglected; and quotations are weaker. There is a little more activity in pitch; and some of the fuel makers are supplying their pressing needs at the advanced prices demanded. Creosote is moving off better; and the prospect for this article is improved. Carbolic acid (crude) is firm; and the same remark applies to anthracene. Prices may be taken as follows:—Tar, according to position, 17s. 6d. to 22s. 6d. per ton. Benzol, 90 per cent., 2s. 11d. per gallon; 50 per cent., 2s. 4d. Toluol, 1s. 6½d. per gallon. Solvent naphtha, 1s. 3d. per gallon. Crude naphtha, 30 per cent., 1s. per gallon. Light oil, 3d. per gallon. Creosote, 2d. per gallon. Pitch, 12s. to 15s. per ton. Carbolic acid (crude), 8s. 5d. per gallon. Cresylic acid, 9d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 6d. per unit; "B" quality, 1s. 3d.

Ammonia Products.—Sulphate is moving off freely, and important shipments are again being made to France. The experience last year evidently satisfied the users there of its superiority to nitrate of soda; the latter article having largely displaced sulphate during the past season. Prices continued firm during the week, at £11 10s. to £11 15s. per ton, less discount. The prices of other products are as follows:—Gas liquor (5° Twaddell), 7s. 6d. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 2d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £27. Sal-ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, Oct. 20.]

Sulphate of Ammonia.—The market keeps very firm; and we hear that makers are holding out for higher values. Business was done yesterday at £11 15s. Hull; but for next month £12 to £12 2s. 6d. is now being asked. There is a danger in running up the prices too rapidly; but if the consumers act wisely, they will cover their requirements early, as anyone with half an eye can see upon what a delicate balance the supply and demand are hung. Sulphate is scarce; and there is no denying this fact. Beckton stands at £11 15s.; while London outside makes are value for £11 13s. 9d. The Leith market is very firm at £11 13s. 9d.

Tar Products.—Benzols are weaker again; and prices are a penny or three-halfpence below last week's quotations. Solvent naphtha is still in good demand—that is, coal-tar solvent; the coke-oven solvent, which was under trial at several india-rubber works, having now been practically abandoned. Crude carbolic is firmer, though without change in price; and "B" quality of anthracene has advanced another penny, and is now valued at 1s. 3d. Good liquid creosote is moving off freely; and the demand will most assuredly be good throughout the winter. Pitch remains much in the same state as in our last report; and prices are unchanged.

FILEY WATER AND GAS COMPANY.—The annual general meeting of this Company was held on Saturday, the 13th inst.—Captain Unett presiding. The report and balance-sheet for the year ending June 30 last was presented, and showed the receipts for both gas and water to have been considerably in excess of any previous year. The work undertaken by the Directors last year in making a new reservoir at Hunmanby and remodeling the works at Filey have been satisfactorily completed, at a cost of £5130; and the Company are now in a position to supply both gas and water of good quality to any extent which may hereafter be required by the townspeople.

CEARA GAS COMPANY, LIMITED.—From the report of the Directors of this Company for the year ended June 30 last, we learn that the rental, both public and private, shows a satisfactory increase. The expenditure on capital account—£2741 6s.—includes 300 additional public lamps, condensers, coal-stores, mains, &c. The accounts show a profit of £4476 13s., which, added to the balance of £675 4s. brought forward, makes £5151 17s. Deducting the interim dividend paid in April, there remains £1001 3s. available for division. The Directors recommend that £1000 be added to the reserve fund, and the declaration of dividends for the six months ended June 30 last at the rate of 10 per cent. per annum on the preference shares (less income-tax), and at the rate of 11 per cent. per annum on the ordinary shares (free of income-tax); making, with the interim dividend already paid, 8 per cent. for the year. The balance carried forward will be £949 12s. 6d.

FEATHERSTONE WATER SUPPLY.—The difficulties which arose some time ago at Featherstone in respect of the water supply of the township have at last ended; an agreement having been come to between the Featherstone Local Board and the Wakefield Corporation for a supply from the reservoirs of the latter authority. It has received the common seal of the Board, as well as that of the Corporation. On the sealing of the document, the Mayor gave expression to the general feeling when he referred to the pleasure it gave him to find that the two authorities had at last come to terms. The hitch in the negotiations, and which so long retarded a final settlement, was the demand on the part of the Board to be guaranteed a supply whether or not Wakefield had sufficient for its domestic and manufacturing purposes. But this demand was withdrawn; and the Corporation also made a concession, whereby the agreement is to remain in force for the term of 30 instead of 20 years. Both sides are to be congratulated upon the compromise.

THE PROFIT OF THE OLDHAM GAS-WORKS.—Mr. H. Andrew, the Superintendent of the Oldham Corporation Gas-Works, writing to a local paper, says: "The sums paid directly by the Gas Committee in aid of the borough rates, during the year ended March 25, 1888, amounted to £13,809 2s. 11d. The entry in the borough fund revenue account would have been correctly stated if it had been given thus:—Interest on the gas-works capitalized profits during the year ended March 25, 1887, £75,438 6s. 11d., at 4 per cent., £3017 9s.; net profits from gas-works for year ended March 25, 1887, £10,791 18s. 11d.—total, £13,809 2s. 11d. The £3017 1s. is included in the amount charged for annuities and interest (viz., £11,844 7s. 6d.) in the gas-works profit and loss account, and also in the item of £4812 17s. 11d. for annuities, interest, &c., accrued to and unpaid on March 25, 1887. The sum of £7973 16s. 4d., being the amount available to be used in aid of the borough rates from the gas profits for the year ended March 25, 1888, has been paid into the borough fund since the 25th of March last, and will therefore be dealt with in its revenue account for the year ending March 25, 1889."

DAMAGING A GAS-LAMP AT BRISTOL.—At the Bristol Police Court last Friday, John Golding and William Burgess were summoned for damaging a gas-lamp belonging to the Bristol Gas Company. The circumstances of the case were very peculiar. On Aug. 13 last, Mr. Golding left his horse and trap unattended in Victoria Street, Temple. The animal started off and came into collision with a horse and trolley belonging to Mr. Burgess, standing by the side of the pavement without anyone being in charge. The two horses ran away; and eventually Mr. Burgess's trolley came in contact with a lamp-post, knocking it down, and doing damage to the extent of £1 16s. 3d. Mr. Carter, who appeared for Mr. Burgess, submitted that he was not liable, and that his driver ought to be summoned, as he was responsible. Witnesses having been called in support of the summons, Mr. Carter contended that there was no default on the part of his client. The Magistrates were of this opinion, and ruled that he was not liable, and dismissed the summons against him. They held that Mr. Golding's horse was the cause of the damage by running away. They expressed sympathy with Mr. Golding, but said he must pay the amount of the damage.

SALES OF SHARES.—On Wednesday last, Messrs. Edwin Fox and Bousfield disposed of a number of miscellaneous shares at the Mart, Tokenhouse Yard, E.C.; among them being 20 £10 fully-paid shares in the *West Kent Gas Company*, on which the maximum dividend of 10 per cent. is being paid. These realized £20 per share; and a parcel of 30 £10 shares (£4 paid) in the same Company, on which the maximum dividend of 7 per cent. is being paid, sold at £6 10s. each. Sixty £5 shares (£4 paid) in the *Bombay Gas Company, Limited*, fetched an average price of £5 15s. The last dividend paid on these shares was 7½ per cent.—On the previous day, Messrs. Nicholson, Greaves, and Barber sold some of the new shares recently issued by the *Sheffield Gas Company*, which are of the nominal value of £6 each, and the first call (£1 4s. each) on which will be made next month. They fetched £4 5s. and £4 6s. 3d. per share.—Last Wednesday, Messrs. Edwards and Sons sold by auction at Stoke-upon-Trent, £20,000 new consolidated stock in the *Staffordshire Potteries Water Company*; being a portion of the £30,000 lately authorized by Parliament. The stock was put up in £100 lots, which realized prices ranging from £140 to £147 each.

SERIOUS EXPLOSION OF GAS AT THE LEEDS MIDLAND STATION.—Between three and four o'clock last Tuesday afternoon, an explosion of gas in a disused kitchen, almost immediately underneath the first-class refreshment room at the Midland Railway Station, Leeds, resulted in serious injury; Richard Collier, a gas-fitter, and William Regan, a labourer (both employed by the Company), being rather badly burnt. An escape of gas had been discovered in the cellars under the refreshment department on the platform on the south side of the station; and the men went to search for the leakage. They disconnected the mains in two or three places, in order to satisfy themselves as to the direction in which the gas travelled. Having completed this operation, they joined up the mains again excepting at one point. In the brief period during which the pipes were disconnected a considerable quantity of gas accumulated in an old empty kitchen. When Collier and Regan were finishing their work, the latter struck a light, which ignited the escaped gas. Collier's clothing took fire; and he was very seriously burned from head to foot. Regan's hands and a portion of his head suffered, though much less severely. Collier was carried to the Infirmary, to which institution his fellow-workman was able to walk. The more seriously injured man lay unconscious all Tuesday evening; and his condition was considered somewhat dangerous. His companion, however, after receiving medical attention, was able to go home.

REDUCTION IN PRICE.—The *Heckmondwike Gas Company* have reduced the price charged for gas supplied to the public lamps to 2s. 6d. per 1000 feet.

PROPOSED ADOPTION OF THE SLIDING SCALE BY THE BRISTOL GAS COMPANY.—At the meeting of the Bristol Sanitary Authority last Thursday, a discussion took place upon a communication received from the Secretary of the Bristol Gas Company (Mr. Jas. V. Green), to the effect that the Directors contemplate applying to Parliament for power to adopt the sliding-scale principle, and asking whether, in the event of such permission being applied for (which it was considered would be advantageous to the consumers as well as to the Company), the Sanitary Authority would concur in the application. Mr. Green pointed out that the Company may now charge 4s. 6d. per 1000 cubic feet; but that the Directors propose to fix the initial price at 2s. 9d., from which figure the sliding scale will operate. He added: "I may say that ½ per cent. on the capital of the Company amounts to £1095, whilst 1d. per 1000 cubic feet amounts to £5084; so that practically out of every saving of £6000 our proprietors would receive an additional dividend of £1000, and the consumers of Bristol would receive £5000." It was decided to inform the Company that the Authority had not had sufficient time to consider the matter to enable them to advise the Town Council thereon, with a view to an application by the Company next session.

THE NORTHERN COAL TRADE.—The northern coal trade is now experiencing increased activity through the apprehension of a strike of some importance in the Yorkshire district. Already some of the southern railways which derive their supplies usually from Yorkshire and the Midlands are negotiating for contracts in the Durham and Northumbrian coal-fields; and hence the price of steam coals is stiffer. Some of the best collieries are now asking 8s. per ton for best steam coal—an advance of 6d. Gas coal is also in brisker demand; and, all round, the users of coal appear to desire to stock more rapidly. Some Italian contracts for gas coal are now being negotiated; but the uncertainty as to the rate of steamship freights affects business. It may be added, too, that in all the coal contracts now the question of the supply of tonnage for carriage is important; and 5s. per ton has had to be paid for freight on coal by steamer to London this week—a rate which is very considerably above that of a year ago, but which is fully justified by the advance which has taken place in other freights. The household coal trade is much more active; but there is no change in prices. The general appearance of the coal trade of the North, however, seems to point to a further advance in rates; whilst the opening of the strike campaign would certainly bring about a rise. Gascoal is now much more abundant; but the cement-works are taking large quantities. Still for three months there will of necessity be increasing supplies.

TUESDAY, OCTOBER 30, 1888.

THE LONDON COUNTY COUNCIL—A PROSPECT.

THE announcement as to the appointment of the Duke of Westminster to be Lord Lieutenant of the new County of London, which was published last week, has served the newspapers for a peg whereon to hang some rather idle speculation as to the future administration of the huge Metropolitan province now about to assume organized entity. Some highly complimentary things have been said respecting His Grace of Westminster, most of which, it is only just to admit, have been fairly earned. The Duke is a Londoner in his sympathies as well as by choice of residence; and there cannot be two opinions about his fitness in every sense for the most honourable and exalted employment in connection with the government of the great capital in which he has probably the largest individual territorial interest. It is a sound instinct that sees in a member of the highest order of the nobility of the land the right person to be first named as an officer of the new Metropolitan executive, and witnesses to the awakening of a sense that what may be called Absenteeism has been, and still is, as great a hindrance to

healthiness of London government as in the familiar example of Ireland. Wherever there exist different grades and classes in a society—that is to say, all over the civilized world—the perfect working of that society can only be ensured by every class and degree performing those functions of the whole organism for which it is best fitted. It is to be hoped that few intelligent students of sociology now retain the exploded opinion that any good can be expected from those violent reclassifications of the members of a community that were so favoured by the revolutionaries who made their last experiments in '48. The time may come when the best of the ideas which are commonly recognized as Socialism will be carried into effect; but if so, it can only be through the working out to their natural result of those processes which in their present stage present to us the spectacle of a society arranged in more or less perfect and separate strata. In a healthy community, whatever may be the diversity of the classes composing it, all are cemented together by common recognition and discharge of public duty, as well as interpenetrated by sympathies arising from unity of race, community of opinions, and multitudes of other similarities and agreements. No layer can be forcibly withdrawn without injury to the rest, although it may be as apparently useless in itself as a vein of quicksand in a sub-soil. Readers of that splendid work of Henri Taine's, "The Ancient Régime," will remember how strikingly the author makes out the connection of the horrors and blunders of the Revolution with the withdrawal of the old nobility of France from the spheres for which they were originally created, and in which they were useful in order to ornament a frivolous Court. The nobles of the Ancient Régime became useless when taken out of the places in which they could have served the commonwealth. Unused members, physiologists tell us, are liable to decay, and even to poison the organism to which they belong. So it was with the France of the old Monarchy; and so it has been, in a very much smaller way, with the London of the Metropolitan Board of Works. Whole classes of the Metropolitan community have abstained from act or part in the administration of the centre of population and influence of which they constituted a portion, to their own loss as well as that of the public. There has been an excuse for them in the muddled and imperfect scheme of London government under the Vestry system; but with the gift of a County Council, this excuse disappears. The question is, Will the new tools of government be taken up by the right hands?

It is a good beginning to select for the Lord Lieutenant of the new Metropolitan county a great nobleman who has earned such respect for himself as even to reflect additional lustre upon his rank; but the Lord Lieutenant is, after all, very much of an Olympian god in the scheme of county self-government; and the question of the acceptability of a county administration will depend upon the elective members, and especially upon the new popular leaders who will be developed under the yet untried scheme. Of what sorts and conditions of men will the London County Council be composed? It is not too soon to ask the question now, when the subject of who are likely to come forward as candidates for election into these bodies is interesting the country generally, albeit in a quiet way. Some people protest against the introduction of party politics into these elections; others assert that unless politics are followed, it will be impossible to procure good men for the Councils. In a recent leading article, *The Times* remarked that "it would be a great and irretrievable misfortune for London if the County Council should prove to be nothing better than an agglomeration of Vestrydom" or a reproduction of the Metropolitan Board of Works." Yet it is tolerably certain that most of the old parochial personages who have so long worked the machine of London Local Government, are quietly preparing to put themselves forward at the proper time for election into the new organization; and it would not be surprising if there should be a good deal of hand-shaking among old cronies, as well as some lobbying in the regular old style, when the Council meets for the first time, and proceeds to the nomination of its different Committees.

The remedy for this possibility of the near future lies in the selection of new and good men for the Council, and in the regular publication of their doings when in harness. Perhaps one or another of the London newspapers that obliges its readers with a daily column of Turf news will condescend to throw about half as much light upon the policy of a Chairman of a Finance Committee of the Council disposing of about a million sterling out of the rates, as upon

the public performances of the wretched "platers" which are religiously recorded in its columns for the edification of its sporting readers. We confess candidly, however, that we scarcely hope for as much. The first selection of councillors for London must be largely hap-hazard, seeing how little the people know of each other, and how divided are their interests between city and suburb. But this drawback can be easily made up if there is only sufficient publicity thrown upon the after-proceedings of the representatives to be chosen so much at random. It is precisely this desideratum, however, which is likely to be lacking. The London daily newspapers might as well be printed in the moon for all the care they usually bestow upon the municipal affairs of the capital; and the various district and weekly publications that profess to keep record of Metropolitan municipal affairs are generally of a quality beneath contempt. If this is amended with the new dispensation, it will go further towards ensuring the good working of the fresh system of local government than anything else that could be named. At present it is a deplorable fact that habitual readers of the principal London daily newspapers are kept better acquainted with the development of the town affairs of Paris, and even of New York, than of the city in which they earn their bread, and in the suburbs of which they have their domiciles.

While it will be of the first importance to get good men and able administrators for the County Council of London, if such can be obtained, it will be almost equally important that the mistake perpetrated in the case of the London School Board should not be repeated. For the first School Board, all the celebrities of the day were candidates. Lord Lawrence was the first Chairman, and Professor Huxley was an ordinary member. Now the Chairman is—the Rev. Mr. Diggle, and the members are nobody knows who. It is possible that Mr. Diggle may be a better Chairman, in his way, than was his Lordship of the Punjab; but the two names cannot be spoken without arousing a sense of that kind of comparison which rightly deserves to be regarded as odious. The fact of the matter is that the first members of the Board were too big or too eminent for the work that was really required; but they did an amount of good in their day by strongly grasping the unknown responsibilities of their new position, and interpreting their duties in a spirit widely different from that in which they would have been understood by (say) a Select Committee of different Boards of Guardians of the Poor. When these eminent personages gave up the work, they were followed by mediocrities who could copy them in nothing but extravagant expenditure; and these naturally gave place to the existing race of economists. This history teaches us to deprecate the choice of too lofty or celebrated individuals for the first London County Council. London wants neither the seasoned vessels of the Metropolitan Board of Works, nor a cluster of ex-Governors, Generals and Bishops out of engagements. A few smart young lawyers would not be amiss; and the same may be said of moneyed scions of good old business firms in want of something to do. If we once embark upon descriptions of eligible candidates, however, it will be impossible to stop. The great thing is that the body, however composed, should be truly representative of all classes of Londoners, from Whitechapel to Belgravia. There is a great deal for the London County Council to do. Even with regard to gas supply and water distribution, it will have a long leeway to make up, without rushing full tilt upon the question of the purchase of the undertakings of the Companies. Yet we must not expect too much at first. "Who goes softly," says the Italian proverb, "goes safely; who goes safely, goes far." The new body will have to feel its way with particular care, having before its eyes the fate of its unhonoured predecessor, and knowing that pitfalls will await it at every step in its advance. If properly constituted, however, of men who for the most part are neither needy adventurers nor senile men who have prospered in trade because they never had an idea out of their business of money-making, the Council may have an honourable and protracted career.

THE COAL QUESTION.

Much attention has been directed during the past week to the question of coal. The owners have conceded the required advance of wages in several districts; the situation in Yorkshire, Derbyshire, and North Nottinghamshire up to the end of the week being stated as follows:—Nineteen collieries, with an output of 10,000 tons per day, were working at the advanced rate; while sixty-nine collieries, with a daily output of 80,000 tons, had refused the advance, and accordingly

the men, with few exceptions, were out on strike. The strike was vigorously kept up in Derbyshire; about 20,000 men being out until last Saturday. On the other hand, the owners in the mining districts of Oldham and Ashton have granted the advance, and all fear of the strike extending to this district is therefore at an end for the time. Although 8000 men are reported as being out in the Leeds district, the miners' agents are confident that the advance will soon be generally obtained. It was announced yesterday that the chief Derbyshire collieries had resumed work at the advanced rate. A great deal of solemn nonsense on the subject of the strike is addressed to the men in some newspapers. They are adjured to think of the interests of the trade of the country, the manifest improvement in which, that has been recognized of late, is said to be imperilled by their action; but bearing in mind how little regard is had to such considerations by the great men who form syndicates and "rings" for their own profit, it is the rankest hypocrisy to tell working men that they should not look after themselves. If mere self-interest is not to rule the men at the bottom of the industrial system, those at the top should not be so prone to act upon the same motive whenever they see the chance. Of course, a strike is a deplorable device for procuring a resettlement of a wages question; but it is evident that workmen are less prone to fly to this their last weapon than formerly. Sorry as we naturally feel to see this interruption of the trade of the country, we do not deny or conceal our opinion that, at least in the gas coal branch of the trade, the men can very well be paid the additional wages; and that if for this purpose the cost of coal should require to be raised by a few pence per ton, Gas Companies and Corporations can easily afford to pay the difference. Several subsidiary questions arise out of this subject of miners' wages and strikes. It may be remembered that a few years ago Mr. C. E. Jones read a very useful paper before the Manchester District Institution of Gas Engineers, in which he argued that if gas coal were ordered to be delivered in equal monthly quantities instead of as wanted for instant carbonization, the strain upon colliery management would be materially reduced, and strikes, which usually come just at the commencement of the winter season, would be largely prevented. We supported this appeal to Gas Companies at the time; but it is to be feared that the objectionable system condemned with so much reason by Mr. Jones is still too general, although at least 3d. per ton can be saved by purchasers who are willing to receive their consignments of coal in regular quantities throughout the year.

Before leaving this subject, it may just be noticed that the irrepressible Mr. Ellis Lever has written to *The Times*, advertising himself, as usual. He says: "I am, as you are aware, a large gas coal and cannel contractor, besides having an interest in colliery companies;" and, apparently out of respect for this claim, the Editor of *The Times* allows him to make some very peculiar statements regarding the gas coal trade. Strangely enough, Mr. Lever then supports what was remarked in the *Journal* last week upon the result of competition and low prices in fostering dishonest practices for the purpose of obtaining orders for coal. He declares—and there is no better authority upon the point—that to secure gas and other coal contracts, commissions of "from 6d. to 2s. 6d. a ton" are paid to those who have the giving or influencing of "orders." When, however, he goes on to state that "it is computed that £800,000 a year is paid in this way in connection with the gas industry of the United Kingdom," one may be permitted to think that he speaks less from personal experience than from a much too exuberant imagination. Mr. Lever next regales the readers of *The Times* with the repetition of the story of his own criminal prosecution for exposing the Hunter frauds at Salford; and continues: "I have lately exposed similar doings at the Halifax Gas-Works"—asserting, moreover, that he "could name scores of towns where the same practices obtain, to the complete demoralization of all concerned." The obvious rejoinder to this boast is, why does he not carry it out, and at once earn his statue as the great and presumably only honest coal dealer of his age? With a fine display of indignation, Mr. Lever concludes this truly remarkable, not to say audacious, letter. He protests, of course in the name of the public interest, against the formation of anything like a Coal Syndicate. The only good we can see in such a project is that it would render middlemen, like Mr. Lever himself, superfluous, which is "a consummation devoutly to be wished;" for it is open to be argued that, whatever evils

might be expected from the working of a Coal Syndicate, they could not possibly surpass the mischief that has been wrought by middlemen. We are ready to admit that all middlemen are not like Mr. Lever; but he belongs to the class, and cannot dissociate himself from it. In connection with this aspect of the question, the letter addressed by Mr. Henry Woodall to the Manchester daily newspapers, and reproduced in another column, will be read with some amount of interest.

THE HALIFAX GAS SCANDAL.

THE Halifax gas affair has entered upon a further stage of its development. We had gathered from the statements of the local press that the immediate result of Mr. T. K. Fox's published libels upon the three persons whose names were mentioned therein would be the commencement of proceedings against the author by Mr. Alderman Riley, and against the Mayor by Mr. E. G. Wrigley. Time has passed on without any such action having been taken. Mr. Riley seemed to be ready for the attack; but he required an indemnity in terms which the Town Council have declined to give; and in default of this he has made no sign of any intention to begin hostilities on his own account. It is useless to deny that this apparent repugnance to avail themselves of their remedy on the part of the libelled persons has made an unpleasant impression even upon that section of the public which was at first disposed to suspend judgment in the matter. It is reasonable that a suspension of judgment should be demanded and obtained when allegations of this order are flying about; but the suspension can only be for such time as may be reasonably allowed for the incriminated persons to act in their own defence. We have all along been disposed to make special allowance for Mr. W. Carr, knowing that his state of health is such that the excitement and strain of an action-at-law might be too much for him. In the case of Mr. Wrigley, we understand that, by the advice of his Solicitor, he is awaiting the commencement of a civil action by the Halifax Corporation, the writ in which he is daily expecting, upon the line of the claims indicated in the now notorious speech of the Mayor. This action will clear the way for subsequent proceedings to be instituted by Mr. Wrigley for the defence of his personal character; but it is considered best, under the circumstances, that the commercial side of the question, as between the coal contractor and the Corporation, should be first dealt with. We are not aware of the nature of the steps, if any, that Mr. Riley will take. If Mr. Riley and Mr. Wrigley could clear themselves of blame, the deliverance would in all probability serve for Mr. Carr also, who is apparently not charged with anything other than what he must have shared with one or both of these his associates. With Mr. Wrigley particularly it is a question of life and death. He has poured contempt upon Mr. Fox; and as Mr. Fox is notoriously only a stalking-horse for Mr. Lever, the treatment is not unmerited. Whether or not the accused persons take action, the matter is to be probed to the bottom. They have had offered to them the opportunity for acting on their own behalf; and the Corporation have declared that, whatever steps are found to be necessary for thoroughly sifting the affair, shall be undertaken in the public interest. If it is of moment to the accused to clear their characters; and it is also of the highest importance to the Corporation of Halifax that the circumstances attending the administration of their gas undertaking should be elucidated. We can only hope that success the most complete and satisfying will attend the efforts of the Town Council in this direction.

THE BRISTOL GAS COMPANY AND THE SLIDING SCALE.

As announced in last week's issue, the Bristol Gas Company contemplated applying to Parliament next session for the sliding scale. The Company have at present a maximum price of 4s. 6d. per 1000 cubic feet, but are actually selling gas at 2s. 4d. They intended to ask for an initial price of 2s. 9d., and notified the fact to the Bristol Sanitary Authority, whom they asked to consent to the figure and the application. This the Authority refused to do, upon the rather transparent excuse that there had not been sufficient time to examine the proposal, and advise the Town Council respecting its desirability or the reverse. The Directors of the Company seem to have been only half-hearted in the matter; for, after making this announcement of their views, they have dropped the idea of going to Parliament, with the Corporation possibly in opposition. This looks, on the face of it, a rather weak style of proceeding. If the Board had really made up their mind that the sliding scale would be a good

thing for the Company, they should certainly have persevered, with or without the countenance of the Local Authority; knowing that if the first House of Parliament put the initial price below the limit which they were prepared to accept, they need not proceed with their Bill in the second House. It seems a pity that, having shown their hand to this extent, they did not decide to make a dash for what they wanted. The incident shows how difficult it would be now for any Company really working honestly under the old legislation to better themselves by adopting the sliding scale. It is not to be expected that the Bristol Company, selling gas at 2s. 4d., would be allowed a sliding scale of 2s. 9d. per 1000 cubic feet. Perhaps they thought of asking for 2s. 9d., with the idea of falling back upon 2s. 6d. as a last resource; but even then it would be very questionable whether there would be any advantage in giving up the safeguard of a 4s. 6d. maximum for an extra 10s. per cent. in the present. And supposing that the initial price had been made equal to the current selling price, would the Company be right in accepting it? "Certainly not," would be the probable answer of the majority of the shareholders, if the position were explained to them. Altogether, it looks very much as though the existing maximum-dividend Companies are likely to continue as such from the lack of means of escape.

THE LATE SIR W. SIEMENS.—The biography of the late Sir W. Siemens, which, as stated in the JOURNAL last week, has been prepared (under the direction of the Executors) by Dr. W. Pole, F.R.S., was issued last week by Mr. Murray. Pending the fuller notice of the book which will appear in an early issue, we may say that Dr. Pole has produced an exceedingly interesting account of the career of one of the most conspicuous of the engineers of the present generation. The late Sir W. Siemens possessed in a high degree the inventive faculty; and the use to which this great talent was put is well shown by his biographer. The volume contains portraits of Sir William and his three brothers, as well as other illustrations.

DEATH OF MR. T. ROWLAND HILL.—We much regret to have to record the sudden death, last Tuesday, of Mr. Thomas Rowland Hill, in his 56th year. The deceased gentleman was formerly the head of the firm of Hill, Higgs, and Hill, Builders and Government Contractors, of Kennington. He retired from the firm, however, some years ago—partly on account of ill-health; relief from business being considered desirable. We believe that members of the Hill family have been shareholders of the South Metropolitan Gas Company for the last 30 years or more; while Mr. Hill himself was elected a Director immediately antecedent to the amalgamation effected in 1879 with the Surrey Consumers' Company. He was regarded by his colleagues as a man of good sound sense and business ability; and during the nine years he was on the Board, he won the esteem of both the officers and his co-Directors. In his private life he was also much respected.

SOUTHERN DISTRICT ASSOCIATION OF GAS ENGINEERS AND MANAGERS.—The next meeting of this Association, which will be held on the 8th prox., promises to be an exceedingly interesting one. In the first place the members will have submitted to them, in a paper by Mr. George Livesey, the important question of the day, from a gas-works constructor's point of view—viz., "How and how far the guide-framing of gasholders may be dispensed with." Next, Mr. W. E. Price, of Hampton Wick, will call attention to some of the hindrances to the sale of gas. The rest of the business will consist, as usual at the November meeting, of the election of President and office-bearers for the ensuing year, and the admission of new members. In view of the dissatisfaction which has from time to time been expressed with the old meeting-place, we are pleased to notice that the Honorary Secretary (Mr. J. W. Helps, of Croydon) has secured the Whitehall Rooms of the Hôtel Métropole for the future gatherings of the Association—an arrangement which will, we are sure, be much appreciated by the members.

MR. ELLIS LEVER AND THE LEEDS GAS COAL CONTRACTS.—Our readers will remember that at the meeting of the Leeds Town Council on the 11th inst. (see *ante*, p. 686) certain communications which had been received from Mr. Ellis Lever in reference to the gas coal contracts were under consideration. No action was taken upon the matter as far as the Council were concerned; but the Gas Committee decided to entertain Mr. Lever's proposal. Accordingly, he had an interview last Saturday week with the Mayor (Mr. Alderman Scarr), the Chairman of the Gas Committee (Mr. Gilston), and the Town Clerk (Sir G. W. Morrison), when the subject of his letters was discussed at some length. The result was that he was invited to test various consignments of coal on their way to the gas-works. On this he was engaged for several days last week; and presented his report to the Committee on Friday. He states that the coal examined was from 6 to 15 per cent. inferior in quality to that submitted when the Committee accepted the tenders; and some tests are reported to have revealed a deficiency of from 20 to 30 per cent. He also condemns the existing system of checking and weighing the coal. After considering the report, a Sub-Committee was appointed to further investigate the matters referred to therein, in conjunction with Mr. Lever.

Water and Sanitary Affairs.

A NEW grievance has been found out by Mr. Archibald E. Dobbs; and he is in ecstasies accordingly. He accuses the New River Company of "inexpressible meanness," "paltry robbery," and "pettifogging extortion," over a matter of 3s.; being the charge in respect to a particular water-closet, which he alleges takes no water from the Company's main, but derives an exceptional supply from an old well. On this phase of the "The Water Question" Mr. Dobbs expatiates in language of the most impassioned character; the world being made acquainted with the momentous topic by means of a letter to *The Times*. Mr. Dobbs is aghast at the audacity of the Company. "Do they think that I am 'dead or dumb, or that my hand is paralyzed so that I cannot write?' Intoxicated with past victories, Mr. Dobbs cannot bear to be ignored. It is true he is not the party who is required to pay the 3s. It is not even clear that the gentleman on whom the demand is made is either friend or neighbour to Mr. Dobbs. But somebody, it matters not who, is called upon to pay; and Mr. Dobbs, as the sworn adversary of the Water Companies, considers his personal dignity compromised. The Companies have ceased to be afraid of him (if ever they were afraid at all); and Mr. Dobbs warns them of the tremendous consequences of their temerity. What is going to happen, we do not know. But Mr. Dobbs is very irate, and New River shares may be expected to fall. Let it be understood, however, that the Company are acting within their rights, though Mr. Dobbs says that, in his opinion, they are altogether wrong. It may be urged that, as a matter of policy, the Company ought not to enforce their claim. But the Directors have a heavy responsibility resting upon them. This is not a mere question of 3s., or they might spare themselves any further trouble. They probably see in this matter, as in other questions that have arisen, that if they surrender their rights in one instance, they may have to do so in all other cases of a similar character. Water Companies have learned by this time the danger of making concessions. If they yield a point, the act of grace is quickly perverted into an abandonment of all such rights for the future. Once gone, they cannot be revived. We must also remember Mr. Dobbs has stated the case in his own way; and perhaps there is another way of telling the same story. An additional bone of contention on which Mr. Dobbs is now "sharpening his teeth," consists in the basis adopted by the New River Company for the water-rate outside the Metropolitan area. It appears that the Company take 10 per cent. off the assessment for the inhabited house duty, and make the remainder the basis for their water-rate. This is much too simple and understandable for the subtle genius of Mr. Dobbs, who desires a troublesome calculation to be entered into for the purpose of ascertaining the "net annual value." Possibly some consumers would gain a trifle by the change; but it is quite likely others would lose, and, on the whole, nobody would be any the better for all the disturbance, except that Mr. Dobbs might plume himself on the ability with which he sets people by the ears. He says it would be a "joy" to him to pursue the matter further by a long disquisition in the columns of *The Times*; but he fears lest the patience of the Editor and his readers should fail. Yet it might be well for all the rigmarole to come out, that the public might see how small a residuum of fact has served as the basis of such an iridescent bubble.

THE Directors of the Commercial Gas Company have elected Mr. W. G. Bradshaw as a member of the Board.

It is reported that Mr. Archibald Dobbs has consented to become a candidate for one of the South Paddington seats on the new London County Council.

THE Liverpool Engineering Society are to-morrow (Wednesday) evening to have read to them, by Mr. R. S. Wyld, jun., M.Inst.C.E., a paper entitled "The Laying of Large Mains."

WE have received from the Secretary of the Institution of Civil Engineers (Mr. J. Forrest) a copy of the new list of members, which has just been issued. In point of numbers, the Institution is probably the largest voluntary association in existence; the roll of members, associate members, associates, and students now reaching 5529.

THE many professional friends of Mr. Alfred Penny, whose relinquishment of his engagements, owing to impaired health, was announced in the JOURNAL some months ago, will be pleased to learn that he is now fairly well. As communications are still occasionally sent to him on gas matters, we may mention that Mr. Penny has removed from Beckenham to Queenwood, Gipsy Hill, Upper Norwood.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET. (FOR STOCK AND SHARE LIST, see p. 772.)

DURING the past week the Stock Exchange markets have, on the whole, been firmer than they were the week before. Still they have fluctuated to some extent, almost from day to day; and they showed no very pronounced change at the close. The Money Market has been easy; and the Funds have fractionally risen. The Gas market was rather quiet until towards the end of the week, when there was a disposition to run against the Metropolitan Companies. This movement had an electric origin; and was aided by the very liberal notice accorded by a portion of the daily press to the preparations being made by an electric lighting undertaking upon a very ambitious scale. One is nothing now-a-days if not sensational; and accordingly this adventure (at least, so it is reported) aims at supplanting gas for a fifth of its cost. Truly a large stride from the three times its cost, which is about the best performance of electricity at present! However, in result, the Metropolitan gas stocks were put down a little; the fall ranging from 1 in South Metropolitan "A" to 2 in Gaslight "A" and Commercial old. Alliance and Dublin was depressed to a slight extent, from a similar cause—an electric project being revived in the Irish capital. Among Suburban Companies, the only noticeable feature is the further rise in Brentfords. The Company will reduce their price by 2d. per 1000 cubic feet from Christmas; thus entitling them to declare an extra $\frac{1}{2}$ per cent. dividend next August. But that is some time to look forward to. The Foreign Companies have been steady; and most of them are particularly firm. Bahia and Metropolitan of Melbourne have slightly advanced. The Bombay Company will meet on the 7th prox.; and the interim dividend of $3\frac{1}{2}$ per cent. will be paid on the 1st of December. The Water department has been exceedingly quiet. Chelsea and Lambeth have been done at low figures; but East London is the better. New River is recovering. The movements in this stock are always interesting. A few days ago business was marked as low as 340; but at the Mart last Wednesday some shares realized as high as 357—with a minimum of 353.

The daily operations were: Very quiet business on Monday in the Gas market; consisting only of three or four transactions in Gaslight and Imperial Continental. One deal in East London was all the business in Water. Tuesday was more animated; but not much. Prices in Gas were only moderate; and Gaslight "A," receded 1. South Metropolitan debentures rose 2. Water was still very quiet, and prices were low. Gas was again inactive on Wednesday, and tending to flatness. South Metropolitan "A" fell 1; and the "B," $1\frac{1}{2}$. But the debentures rose 1 higher. Water was quiet and unchanged. There was more activity in Gas on Thursday, with a tendency to weakness among the Metropolitan issues. Commercial old fell 2; but Brentfords old and new improved 1 and $2\frac{1}{2}$ respectively. Water was as before. Friday was the busiest day of the week for Gas—especially Gaslight "A" and all three issues of South Metropolitan. Prices were run down rather low; but the only change in quotation was a relapse of 1 in Gaslight "A." Bahia buyers were 1 higher. Nothing at all was done in Water; but New River buyers advanced 5. There was the usual quietude on Saturday; and Gaslight "A" was not even touched. Alliance and Dublin fell $\frac{1}{2}$; and Metropolitan of Melbourne rose 1. Nothing was marked in Water; but East London advanced 1.

ELECTRIC LIGHTING MEMORANDA.

GAS AND ELECTRIC LIGHT IN DUBLIN—A DISAPPOINTMENT AT EXETER—THE PROGRESS OF THE DEPTFORD ELECTRICAL SUPPLY WORKS—THE BUSINESS OF THE EDISON AND SWAN COMPANY.

THERE is another "difficulty" between the Corporation of Dublin and the Alliance and Dublin Consumers' Gas Company; this time in respect of electric lighting. The Company have a passage in their Act of Parliament which authorizes them to supply "artificial light;" and for some years past they have persisted in attaching to these words the signification that they cover the supply of electric light. The Electric Lighting Act takes no cognizance of the position of the Dublin Gas Company, but demands that they should proceed by Provisional Order, like any other speculators in this line. This the Company have given notice of their intention to do; and, naturally, the Corporation have formed a similar resolve. Consequently, the Company and the Corporation are placed in direct competition with each other—a situation which the national mind, as represented in the *Freeman's Journal*, finds exactly suited to its taste. Now that Donnybrook Fair has become a mere memory, the gentlemen of Dublin must have their bit of excitement somehow; and, to the credit of the Gas Company be it spoken, they are always ready and willing to oblige by treading on the tail of the Corporation gowu. *Arcades ambo!* As to the merits of the question, that is a minor consideration; but there will be a rattling good fight, anyhow. We are loth to quit the subject without expressing the opinion that the Gas Company had far better leave the electric light alone, and cultivate their own proper business. They cannot expect to make any money out of it; and from their point of view, it will be better for the Corporation to throw away money upon electricians rather than that the shareholders' cash should be squandered in the way proposed.

Exeter is one of the places chosen by the West of England champion of electric lighting, Mr. Massingham, for carrying on the

campaign which he began at Taunton. A local Company was formed some time ago; and, by dint of a good deal of agitation, the Corporation were persuaded to institute inquiries as to the possibility of lighting the streets by arc lamps. Of course, before the figures were forthcoming, the ratepayers were assured that electricity could afford them a better light at a less cost than gas. Tenders for the street lighting were accordingly invited; and the result is to frighten the Local Authority as well as the people. Taking the basis of a seven years' contract, the offers for supplying 65 arc lamps ranged from the Brush Company's tender of £43 down to the Exeter Electric Light Company's quotation of £22 17s. 6d. per lamp per annum. As the lowest offer is very much dearer than the cost of gas, however artfully the comparison may be made, the idea of adopting electric lights, never very warmly taken up by anybody outside Mr. Massingham's own party, has been abandoned. It is hard to see what the Exeter Electric Light Company can do now, except quietly retire from public view. As we ventured to predict some time ago, at this rate the enterprising promoter of these West of England electric lighting companies, which do not light, must be quickly nearing the critical period when he will be fain to confess that it was an evil day for him when he gave up selling boots and shoes and devoted himself to electricity.

Progress is being made at the Deptford station of the London Electric Supply Corporation, the outcome of the Grosvenor Gallery experiment. Great things are prophesied of this undertaking, which is to be the largest electrical generating factory in the world, and to exhibit the most powerful steam-motor plant ever collected upon one site. We are not disposed to say much about this venture until it arrives nearer completion. A noteworthy feature of the Deptford scheme is the clever idea for running the main conductors from the station into London by obtaining wayleave of the Southern railway companies. The works have a river frontage for convenience of coaling, and bringing materials by water carriage; and only about half a mile of underground piping will be needed to connect them with the South-Eastern Railway Station. Thence it will simply be a matter of running a half-inch copper rod along the various railway lines terminating at different points in town from London Bridge to Victoria, with the District Railway to give access to Kensington and Westminster. So far the scheme is very well thought out. One cannot help respecting the Grosvenor Gallery electricians for the quietness and business-like way in which they have gone about their work, building up a connection piece by piece like any other commercial interest. In this respect they compare most favourably with that other school of projectors, whose public appearances and pretensions have been in inverse ratio with the amount of work they have done, and who are so much better at lecturing and talking to newspaper reporters than at real business.

The fifth annual report of the Edison and Swan United Electric Light Company, referring to the accounts of the concern for the year ending June 30 last, states that the sale of lamps progressed in a satisfactory manner during the year, and the volume of the Company's general business likewise increased; the result being a credit balance of £25,123. This is a very bold statement; and it will be advisable to wait for the shareholders' meeting, and what is said thereat, before forming any opinion upon this figure. The Company wisely restrict themselves to the manufacture and sale of lamps and plant, and do some ship lighting, but eschew lighting contracts. In this respect they differ from the American Edison Company, who, as is well known, have a lighting business in New York which they claim to be very profitable, although the plant was laid down at a time when every electrical fitting cost twice as much as it would at present. The New York Company also claim that, although they have been lighting their district direct from steam-engines and dynamos for over five years, there has never during all this time been the slightest interruption of the supply. Security is obtained by dividing the work of generating the current among a number of engines and dynamos, so connected that if any one or two of them should break down the others would instantly make up the deficiency of current. After their abortive Holborn Viaduct experiment, the English Edison Company quietly withdrew from the attempt, if they ever intended such a thing, to rival their American prototype in the work of lighting; and confined their energies to lamp making, which, diversified by litigation, has fully occupied them ever since.

GAS ACTS FOR 1888.

The timely communication from Mr. William Livesey upon the subject of parliamentary regulations respecting Gas Companies applying for statutory powers, will serve as a preface for our customary summary of the results of the gas legislation of the past session. In stating the amounts of authorized capital and borrowing powers, it must be understood that these are subject to the considerations set out by Mr. Livesey. As he has pointed out, gas legislation is at present conducted upon a very confused system, if system it may be called. The sliding scale and auction clauses have been enforced upon, and adopted by companies for many years; and nobody has paused to inquire how the principles of these modern importations into gas legislation agree, or are in conflict with, the General Acts in conjunction with which they are applied. There are questions affecting the reserve and insurance funds of gas undertakings which have never yet been authoritatively settled. Under the old legislation the reserve fund was taken out of revenue, and therefore belonged to the undertaking as a whole—we will not say, belonged to the consumers, because

any such general statement might be open to misunderstanding. Under the new dispensation, the reserve belongs to the shareholders; being composed of money applicable to dividends, but which they have denied themselves from providential motives. Many Gas Companies, however, have reserve funds made up in both ways; and nobody can say, in all strictness, what might be the result of a judicial examination in such cases. Mr. Livesey's remarks upon the incidence of the ordinary terms of the sliding scale—"a quarter per cent. for a penny"—upon capital issued at different nominal rates of dividend are not new, as he admits; but they are worth repeating until they receive their due consideration. The compulsory issue of new and additional capital as 7 instead of 10 per cent. stock is clearly a survival of the letter of an obsolete law; and Mr. Livesey shows how unfairly it works in practice. Experience shows, however, that legal inconsistencies such as this, and even more serious legal wrongs, are left to linger for a long time, mainly because it is nobody's business to set matters right. We are therefore warranted in predicting that gas legislation will continue for some time to come to be the "thing of shreds and patches" which Mr. Livesey shows it to be. None the less, however, is it incumbent upon Gas Companies seeking fresh or further statutory powers to strive, by carefully drafting their demands, to minimize the effect while recognizing the existence of these parliamentary inequalities. With these preliminary observations, we revert to the actual gas legislation of the year; remarking to begin with that it is small in quantity, and not by any means exceptional in quality.

The Draycott Gas Act dissolves and reincorporates a limited Company formed in 1887 for the purpose of purchasing gas-works then supplying the township of Draycott, in Derbyshire. The capital of the limited Company consisted of £20,000 in £5 shares, of which one-half were fully paid up; and there was no loan. The statutory capital is stated at £20,000, one-half of which (being the amount actually paid up) is the original, and the remainder is to be the additional capital, to be raised, when required, under the auction clauses. Borrowing powers are conferred to the extent of £2500 in respect of the original capital, and of one-fourth of the additional capital actually issued. The sliding scale is imposed, with 4s. 6d. per 1000 cubic feet as the standard price for gas supplied within a radius of 1250 yards from the centre of the existing gas-works, and 5s. beyond. These were the rates asked for in the Bill. Gas of 15-candle power is to be supplied; and it is not, unless in case of unavoidable cause, to contain more than 25 grains of sulphur in 100 cubic feet, as ascertained by the Referees apparatus. The Company may allow not exceeding 10 per cent. discount for prompt payment or in consideration of large consumption, provided that all consumers are treated alike. The Frodsham Gas and Water Act dissolves a limited Company formed in 1856 for supplying gas in the town and parish of Frodsham, Cheshire; the share capital being £5000 fully paid, and £1200 having been borrowed on mortgage. The limits of the statutory Company are enlarged and defined. The gas capital consists of the original £5000 with £15,000 additional under the auction clauses; power being given to raise £1250 by borrowing upon the security of the old capital, and one-fourth of the amount of the new capital as issued. The sliding scale is enacted, with 4s. 7d. and 5s. as the initial prices per 1000 cubic feet for 15-candle gas supplied respectively within and beyond a radius of one mile from the present works. The Henley-on-Thames Gas Act incorporates a limited Company formed in 1834. The share capital consisted £7500 all paid, and there was no mortgage debt. But the works had been extended out of revenue; and at the time of application for statutory powers were valued, with the working capital, at £13,600. The capital of the incorporated Company is to be £24,000, of which £12,000 is regarded as original capital; being made up of the £7500 old share capital of the limited Company, and £4500 to carry 5 per cent. dividend created in respect of moneys expended upon extensions and improvements. In the Bill the Company asked for £33,600 capital, including an allowance of £6100 for improvement capital. Borrowing powers are granted to the extent of £3000 upon the original, and a like amount upon the additional capital. Gas of 15-candle power is to be supplied under the sliding scale, at a standard price of 4s. 4d. per 1000 cubic feet; the illuminating power to be tested upon the works. The Bill asked for an initial price of 5s. per 1000 cubic feet for 14-candle gas. Gas supplied to the public lamps is to be charged for at the lowest price demanded for the time being of any private consumer. Interest at the rate of 5 per cent. is to be paid on consumers' deposits. The Keswick Gas Act reincorporates with further powers a Company formed in 1845. The capital consisted of £9250 all paid up; and there was no loan. The limits of the statutory Company are the boundaries of the parish of Crosthwaite, Cumberland. Their capital is fixed at £20,000, whereof £9250 is the original capital; and there is power to borrow £2300 in respect of the original, and one-fourth of the amount of the additional capital actually paid up. The standard price for 15-candle gas under the sliding scale is 4s. 3d. per 1000 cubic feet within the district of the Local Board, and 6s. beyond. The Bill asked for an initial price of 4s. 6d. per 1000 cubic feet within the Local Board district. Discounts to consumers of 10 per cent. are sanctioned; and 4 per cent. interest is to be allowed on deposits. Where the Company deem it necessary to do so, they may require prepayment for gas supplied for short periods of six months and under, and may refuse to supply unless the estimated cost thereof is so prepaid; allowing 4 per cent. interest on the amount of all such prepayments. For the protection of the

Keswick Local Board, it is enacted that seven public lamps are to be provided and kept lighted by the Company free of charge; and that, if the supply of gas to the other public lamps is by meter, the price to be charged is not to exceed the lowest rate paid by any private consumer. The Riddings District Gas Act incorporates a Company to take over gas-works conducted by the firm of James Oakes and Co. The capital of the Company is fixed at £30,000, with power to borrow £7500. It is enacted that the Company may, if they think fit, undertake electric lighting, under the provisions of a Licence or other sanction issued in accordance with the terms of the Electric Lighting Act. The maximum price of gas is to be 4s. per 1000 cubic feet; and the illuminating power, 14 candles. In the event of any meter used by a consumer being found defective, the error is to be deemed to have arisen only during the current quarter of the year in which the meter is tested, unless the contrary shall be proved to the satisfaction of the Inspector. An agreement between Messrs. Oakes, the owners of the property, and Mr. Charles Horsley, for the Company, providing for the transfer of the gas undertaking for the sum of £18,000 is scheduled in the Act.

There were no Gas Companies in Parliament last session for the extension of statutory powers, with the exception of the Edinburgh and Leith Company, which is represented now by the Edinburgh and Leith Corporations' Gas Act. This Act provides for the incorporation of Commissioners, comprising the Lord Provost of Edinburgh and the Provost of Leith, with fifteen persons to be elected by the Corporation of Edinburgh and six by the Corporation of Leith, to be entitled "The Edinburgh and Leith Corporations' Gas Commissioners." The Act defines the method of election, and describes the procedure of the Commissioners. The agreement dated Nov. 8, 16, and 18, 1887, between the Corporations and the Edinburgh Company is confirmed; and the agreement dated June 29, 1888, between the Corporations and the Leith Company is also confirmed. The particulars attending the transfer to the Commissioners of the two undertakings are stated. On the days of transfer the Commissioners were to pay to the Edinburgh Company the sum of £27,000, and to the Leith Company £11,000, upon which payments the properties were to change hands, subject to the payment of annuities to the shareholders as set forth, and with the exception of cash in hand, book debts, and securities representing cash. The Commissioners also paid for stores and stocks. Sums paid by either Company on account of capital between agreed dates and the dates of transfer are to be repaid by the Commissioners. It is recited that the annuities to the Edinburgh Company's shareholders are at the rate of £10 per cent. upon £200,000; and to the Leith Company's shareholders after the rate of £9 6s. 8d. per cent. per annum upon £150,000. All or any of the annuities are to be redeemable after Nov. 11, 1908, at the price of 28½ years' purchase. Gas of 20-candle power is to be supplied at rates, to be fixed from time to time by the Commissioners, that will bring in sufficient revenue to pay the expenses of the undertaking. Any unforeseen deficiency is to be made good by a Guarantee Fund. Consumers removing are to give written notice to the Commissioners, under risk of remaining liable for gas consumed upon the premises up to the next usual period for ascertaining the register of the meter. The sum of £300,000 may be borrowed on mortgage of the undertaking.

Among minor Acts passed, the Glasgow Corporation Act enables the Corporation to enlarge their gas-works, and to make certain railways and roadway diversions. Land required compulsorily is to be taken within two years. The borrowing powers of the Corporation are extended to £560,000. The Lancaster Corporation Act extends the Corporation gas undertaking. The Nelson Local Board Act confirms an agreement entered into by the Board for the purchase of the Brierfield Gas-Works, and enacts that consumers of more than 200,000 cubic feet of gas per annum in the Brierfield district shall not pay more than consumers of like quantities in the Nelson district; while smaller consumers are only to pay 3d. per 1000 cubic feet more in Brierfield than in Nelson. As between the Local Boards of Nelson and Brierfield, the Nelson Board, as owners of the gas-works, are not to make a higher profit than 10 per cent. upon £65,000, and 7 per cent. upon the remainder of a capital sum of £100,000, not deducting repayments under any sinking fund; and the Brierfield Local Board are to occupy with reference to the Nelson Local Board the privileges of the "gas ratepayers" under the Gas-Works Clauses Act of 1847. The Perth Water and Gas Act provides for additional lands to be taken for gas purposes, and enacts that the illuminating power of the gas supplied by the Perth Commissioners shall be 25 candles, tested at the works.

THE QUALITY OF THE PARTICK, HILLHEAD, AND MARYHILL COMPANY'S GAS.—Our attention has been called to the statement reported, in the JOURNAL last week, to have been made by Bailie McFarlane, in the discussion in the Glasgow Town Council on the proposed purchase of the Partick, Hillhead, and Maryhill Gas Company's works, to the effect that the illuminating power of the Company's gas had been at times as low as 14½ candles, as compared with the Corporation gas at about 23 candles. We are assured that some mistake must have been made by the speaker, inasmuch as the quality of the Company's gas has rarely, if ever, been below 18 candles. We may mention that, in the course of his reply, the Lord Provost remarked that though the gas was not up to the Corporation standard, there was no evidence of any serious complaints having been made in respect to it; and this he regarded as an important consideration.

Notes.

THE SCHÜLKE GAS-LAMP.

In a recent number of the JOURNAL (*ante*, p. 510), we gave a short description of the small type of the above-named lamp, which appeared to us to possess many points of exceptional merit. We have since had a lamp under our immediate notice; and the opinion previously formed of it has been fully confirmed. The makers, however, have determined to make the lamp fitted in every way for domestic use, and have added two slight features which will recommend themselves strongly to practical men. First, by the addition of a small tap, forming part of the lamp itself, the right quantity of gas is admitted to the burners to enable the lamp to be lighted at the top of the chimney by a taper or electric lighter, without moving the recuperator body; and free from any detonation. This tap also affords a ready means of turning the flame down for a small light. The downward radiation of heat from the concentrated light of regenerative lamps is well known; but where the lamp is fixed in close proximity to a person reading, this radiation of heat is admirably checked in the case of the Schülke lamp by a clear glass bowl, which cuts off nearly all the heat, but allows the light to penetrate freely with very slight loss. Both these devices add largely to the practical utility of the lamp, which is rapidly making its way into general use.

AN AMERICAN LOW-POWER GAS-ENGINE.

A new gas-engine, called the "Little Wender," is now being introduced in the States by the Cornell Engine Company, and samples of it are on show at the Chicago Inter-State Exposition. It is claimed that it is the first engine ever made with a rocking-valve that gave satisfactory results in working. In this way much friction is saved over the use of slide-valves; and the power of the engine is correspondingly increased. The gas and air are mixed on the outside of the cylinder, and again inside; the combustion (by a Bunsen burner) being in this way improved, so that the exhaust may be discharged without offence into a room. The valve-box and plate are built square; but all the other parts cylindrical. The engine gets an impulse at every stroke of the piston (like a single-acting steam-engine); and it uses ten parts of air to one part of gas. As to the power developed, 1½-horse power has been indicated on a 1-horse engine running at 180 revolutions of the fly-wheel per minute; and it is said to readily double its power of feeding it up to 600 revolutions per minute—a certain explosion occurring at every turn of the wheel.

A HYDROCARBON VAPOUR GENERATOR.

A new gas-making apparatus, named the "Thermogen," has been patented by Mr. Charles Hearson, and is well spoken of by a writer in *Industries*. It is essentially an apparatus for vaporizing benzine or other volatile hydrocarbons, with the object of afterwards using the vapour in a gas-engine. The vapour is produced in such a manner that it can be made available for supplying a gas-engine without any alteration of the mechanism. A small generator standing 18 inches high, and costing a few pounds, will supply vapour enough for a 2-horse power engine. It gives off the vapour as required; stopping the process of evolution when the engine stops. It is self-contained and self-regulating. In application it consists of a boiler, retort, generator, and mixing chamber. The generator is simply a vertical tube kept red hot by burning round it at the lower end a small portion of the vapour as formed. To start the apparatus, the tube must be first heated from an extraneous source; and this is done by lighting a little methylated spirit in a place provided for the purpose, after which the arrangement is automatic. The oil or spirit is supplied by gravitation under a head of about 8 feet. The vapour as formed escapes into the mixing chamber, which consists of a thin metal cylinder with holes round the circumference at top and bottom. This contains a loosely fitting piston, and is surrounded by a sliding shield, the object of which is to provide means whereby the composition of the vapour may be varied by altering the proportion of air admitted. Any required degree of richness in the "air-gas" delivered to the engine may accordingly be ensured by adjustment of these parts of the apparatus. The description reads rather complicated; but the apparatus is said to be very simple and adapted for ordinary working, being well made and readily cleaned.

FIREPROOFING TEXTILE FABRICS AND TISSUES.

In a recent number of the *Revue Industrielle*, M. Philippe Delahaye made a few remarks respecting the fireproofing of materials placed in proximity to sources of heat, such as gas-flames used for lighting scenery in theatres, &c. Quoting the chief of the Municipal laboratory, who has had this question under examination for a lengthened period, it is made to appear that to render light tissues unflammable is no easy matter. Gay-Lussac laid down the laws of the problem in 1821, by showing that during the action of the heat the tissue must have its filaments protected from contact with air, and also that any combustible gases driven off from a tissue by heat must be mixed with other gases difficult of combustion, so as to be unflammable. The first condition is realized by covering the tissue with some very fusible substance, which upon the first approach of heat will envelop all the surface in a more or less vitreous coating, incapable of evaporating or drying under the prolonged action of a more elevated temperature, and consequently completely isolating the fibre from the air. A great number of earthy and mineral salts proposed for this purpose have given bad results, because under the action of prolonged heat they

leave dusty residues, not capable of sufficiently preventing the access of air; and accordingly combustion has ensued after an exposure more or less prolonged. Substances fusible with difficulty are, on the other hand, unavailing; as they do not melt quickly enough to protect a fabric before it ignites. Further among fusible substances it is necessary to eliminate such as are efflorescent, which after a time fall away in powder; such as are volatile at low temperatures; and those that are too hygroscopic and remain damp. Among the substances which satisfy the first condition without altering by excess of dryness or humidity, are boric acid, alkaline borates, phosphates, and alkaline tungstates. Ammoniacal salts satisfy the second condition of vaporizing with production of unflammable gas. Although less certain in effect than the employment of incombustible materials, rendering tissues inflammable with difficulty is a method calculated to contribute to the public safety. The question of the best process to be adopted with this intent is a very serious one, for upon its satisfactory solution depends the acceptability of gas lighting for theatres in some countries where the Government takes a parental view of its responsibilities for regulating places of amusement.

AMERICAN v. ENGLISH PRACTICE IN ELECTRIC LIGHTING.—Writing on the 13th inst., the New York Correspondent of *Industries* says: "The rough-and-ready manner in which American electric light engineers set to work when erecting distributing plant has been repeatedly criticized in England; and the opinion seems to prevail with you that while our stations and machinery are extremely good, our line construction is inferior. I regret to say that this opinion is perfectly correct. The experience gained in the construction of telegraph and telephone lines has not been utilized as it should have been by electric light engineers; and this has brought about the present agitation against overhead lines. The leniency of the public in permitting electric light companies to erect distributing plant in a most temporary manner, is one of the reasons why the development of electric lighting as a business investment has been more rapid in this country than in England. I think Professor Forbes is in error when he attributes this development to the greater technical knowledge of our capitalists. I do not deny that certain capitalists have been aided by their own technical knowledge; but the main reason of our commercial success in electric lighting is that the principle of *laissez faire* has been allowed to rule to an extent which, from the point of view of public safety, is almost reprehensible."

AN ELECTRIC LIGHTING STATION AT DEPTFORD.—Last week, at the invitation of the Directors of the London Electric Supply Corporation, a large party of gentlemen connected with the Press paid a visit to Deptford, for the purpose of inspecting the buildings and other works which are in course of construction there with the object of forming a central station for the supply of electricity to all parts of London. The buildings consist of one boiler-house and two engine-houses, occupying a space of 210 feet by 195 feet, and having a height of nearly 100 feet. The boiler-house is constructed to contain boilers of 65,000-horse power; and of these a number are being erected to provide steam for engines of 13,000-horse power. In one engine-house a pair of small engines of 300-horse power will be erected in the course of a few weeks for the purpose of actuating two Ferranti dynamos, each of which is capable of supplying a current for 25,000 lights; while in the other will be placed two engines with dynamos, each capable of providing for 200,000 lights. The lines laid down are for the eventual supply of 2,000,000 lights—a maximum which it is expected will be eventually reached. The Corporation already supply electricity to a large number of public and private establishments; and they aim at providing all comers with what they require for lighting or motive purposes. Way-leaves have already been obtained affording entries to the northern part of the Metropolis by several different routes; and the work of main-laying is being pushed forward. The station, both architecturally and mechanically, has been designed by Mr. Ferranti.

DEATH OF MR. JULES PAZZANI.—The Imperial Continental Gas Association have been inopportunistly deprived of one of their ablest Engineers through the sudden death of Mr. Jules Pazzani, M. Inst. C.E., which took place, after an illness of only a few hours' duration, at Amsterdam, on Sunday, the 21st inst., as the result of apoplexy. The deceased gentleman, who was only 47 years of age, had been in the service of the Association for nearly 30 years. During the greater portion of this time, he filled the position of Assistant Engineer at Vienna, of which city he was a native. In 1880 he left Vienna to take charge of the Association's works at Rotterdam. The conclusion of a new contract with the Municipality of Amsterdam, about five years ago, necessitated the erection of new works, and the laying of an entirely new system of mains; and Mr. Pazzani was elected to the important duty of superintending the carrying out of the works. We believe that the Association's Nieuwer-Amstel works (a plan of which was given in the *JOURNAL* for July 6, 1886) were designed by Mr. Pazzani; and they reflect great credit upon him as an Engineer. His demise will be the more keenly felt by the Association, seeing that it followed very closely upon that of his predecessor at Amsterdam, Mr. Miltner. The deceased leaves a widow and rather large family to mourn his loss. His uniform courtesy and kindness gained for him many friends, who will greatly miss him. The funeral took place last Wednesday, and was numerously attended. Several representatives of the Town Authorities and of the Dutch Association of Gas Managers were present; and the coffin was covered with beautiful wreaths.

Technical Record.

THE GASHOLDER GUIDE-FRAMING QUESTION.

AN AMERICAN REVIEW OF THE DISCUSSION.

[The last number of the *American Gaslight Journal* contains the first of a series of articles by Mr. W. Mooney, C.E., dealing with the question of the possibility of dispensing, wholly or partially, with the guide-framing of gasholders. As from a constructional standpoint, this is the most important matter now engaging the attention of gas engineers, we reproduce the communication, which, as it brings under review, in a concise form, the main points in the discussion which has for some time been going on in our columns, will doubtless be acceptable to our readers, seeing that it will enable them the better to approach the consideration of the further developments of the subject which will from time to time come before them.—ED. J. G. L.]

An article with the title "Is Lofty Guide-Framing Necessary for Large Gasholders?" which appeared in the *JOURNAL OF GAS LIGHTING* for March 29, 1887, has brought out various conflicting opinions from several engineers; and as the article seems to have awakened renewed interest in a popular subject, the controversy has probably not yet ended. In fact, it is probable that the author little knew what interest would be aroused by its publication, and what actual results were to arise from it. At a period in the history of gas lighting when holders were being made larger than before, it only needed someone to start the subject to arouse the latent interest which has shown itself in the pages of the *JOURNAL* for nearly a year. It is proposed in the present article to review the arguments upon the subject, as briefly as possible; and, as they all sprang from the publication of the first article above mentioned, a short statement of the position taken by the author will be given.

At the beginning of the article, some hints are thrown out which lead to the belief that Mr. Livesey had already taken some steps toward dispensing with the guide-framing in some three-lift holders lately built, but to what extent the writer is silent. Then follows the statement that "during the coming summer (1887) a gasholder at the Rotherhithe works of the South Metropolitan Company will be altered by the addition of a third lift, *without raising the guide-framing to the additional height.*" The writer further adds: "The saving by dispensing with the framing for the additional lift will not, in this instance, be great; but behind it lies the whole problem of the utility and office of guide-framing in general." He then briefly explains the objects and requirements of guide-framing, as follows:—"It is primarily to provide a means of guiding the moveable vessel along its vertical path. . . . The first conditions of such an arrangement are rigidity and truth of line. Both ends of the line of railway must be as steady as they can possibly be made. . . . In order to be of any service at all, this guiding structure must not only be rigid, but must preserve its rigidity under the greatest stress that can be brought upon it. . . . According to this theory, every gasholder in England ought to be a wreck before the week is out."

After this startling statement, the writer puts forth the following, in all the added weight of italics:—"It is impossible to construct a framework strong enough to uphold a gasholder of any considerable size, without depending upon the inherent stability of the holder itself." He then continues: "There is in the construction of gasholders a point, depending entirely upon their bulk, beyond which these structures are wholly independent of the exterior framing with which it is at present thought necessary to provide them. If this were not true, the erection in the open air of holders surpassing 40 to 50 feet in diameter, and 30 to 40 feet high, would have been impossible. As soon as this limit had been passed, every gale would have swept the land clear of gasholders, and the larger ones would all have been enclosed in storm-proof buildings." This statement is really saying, in other words, that large holders hold themselves up without aid; or no large holder exists in which the guide-framing is strong enough to resist the pressure of the wind without the aid of the holder itself.

The writer then goes on to say, in effect, that he believes the only framing necessary for guiding large holders is a framework standing a few feet above the water-level in the tank, or, at most, to the height of the inner lift. As the difference between these two points in a three-lift holder would be great, it is probable that the writer meant to say to the height of the outer lift. Continuing, he says: "The only good effect of all devices of columns, girders, diagonal ties, and the rest of the usual elaborate guiding structure, is to transmit the strain to the ground as directly as possible. There is no strength in the members up in the air. All they are good for is to preserve a rigidity of form, and to send their burdens down to earth without getting forced out of shape in so doing." The writer, after asking the question, "Why employ elaborate and costly independent framing to transmit to earth the sideways pressures of a gasholder, when you have the holder itself to do it?" answers it thus: "In every large holder yet extant, stability has proceeded from two factors—dead weight and tight bottom rollers. Without these, no outside framing that was ever erected could save a holder from wreck by the first sou'-wester; with them, the outer guiding structure becomes of minor importance." Concluding, he says: "At its base, not at the top, is the place whence the stability of a gasholder must be provided for, if at all."

The very first notice of, or reply to, this article comes from

Mr. V. Wyatt.* After disagreeing with the previous writer in some things, he finally agrees with him to this extent: "Gasholders can be constructed to work well with the external framework carried up only a short distance—say, about 10 feet above the wall coping of the tank; and *perhaps* without any external framing at all. Modification of the lower curb and the cup-and-grip junctions of telescopic gasholders properly spliced may effect this; but the present form of construction, *minus* the external framing, will not be enough. I quite anticipate the production of a self-sustaining gasholder in the future."

Mr. H. E. Jones, in a short letter commenting on the above ideas,† thinks that the drawback of any device dispensing with the guide-framing would be to increase the weight of the floating part of the structure, which is heavy enough already.

Mr. G. Livesey, who would naturally be in the foreground in such a controversy as this, is the next to write on the subject.‡ He thinks the writer of the original article goes too far, and proves too much—that, in fact, he has got slightly beyond his depth, and that much stronger proof than the writer gives is needed to show that large gasholders can work wholly independent of exterior framing. He says: "If some *practicable* means could be devised whereby all the bottom rollers might be made to rise or fall equally . . . the holder would then, to all intents and purposes, have a solid foundation, and no columns or guide-framing of any kind would be necessary. As, however, there are no known means for keeping the bottom rollers in the same level plane, we must, until a better way has been shown, prevent tilting by means of tiers of rollers placed a certain vertical distance apart on the sides, working against guide-framing . . . I am not prepared to say that, if only two tiers of rollers are used, they should be placed at a less vertical distance apart than one-fourth of the diameter of the holder at the top and bottom of the outer lift. This will necessitate external guide-framing to a corresponding height; and such guide-framing is also essential for guiding the inner lift until it is cupped . . . To expect the inner lift to rise and fall satisfactorily when guided only by the rollers on the cup is out of the question; it must have rollers on the crown curb, working in the external framing, to guide it until it is cupped, when a two-lift holder would no doubt work with perfect safety without further support from the guide-framing . . . I should with a three or four lift holder consider it necessary to carry the guide-framing to the height of two lifts; so that the second might be cupped before the rollers on the crown curb left the guides. In short, a holder cannot be considered safe unless it has at least two sets of rollers, at a considerable vertical distance apart, working against perfectly firm guides." In concluding, he sums up by saying: "The utmost I expect to see is, for a double holder, guide-framing not less than one lift high, and for a three or four lift holder, guide-framing not less than two lifts high; and I much doubt whether anyone will attempt to go beyond this."

The next article—from Mr. Hunt, of Birmingham§—contains nothing of importance, and concludes by saying: "If I ventured to express a definite opinion upon so speculative a subject, it would, as regards telescopic holders, be adverse to the proposal of the writer, mainly because it seems to make no adequate provision for the safe working of the inner lift, when this happens to be uncupped. In the absence of any simple and efficient substitute, we have to fall back upon external guide-framing, at least equal in height to the depth of the lift, for effecting this object." In the same number of the JOURNAL, Mr. W. Mann states that a three-lift holder was erected in London, several years ago, by the Phoenix Gas Company, having guide-framing only two lifts high. He, however, says he never knew how it worked, or what became of it. Mr. John Somerville, in the JOURNAL for May 26, 1887, supplies the missing facts; stating that he has ascertained that the holder above mentioned was a failure. It was never cupped, and was changed to a double-lift; and, after a few years' use, was finally taken down (in 1882) with other holders, presumably to make room for other structures.

The next writer on the subject is Mr. W. H. Y. Webber, whose paper was read at the twenty-fourth annual meeting of The Gas Institute, held at Glasgow in June, 1887.¶ The writer states that the purpose of his paper is to show "that the ordinary lofty guide-framing of gasholders may be safely dispensed with, and its place supplied by a system of *guiding from the base*, which may be shortly described as a development by a duplication of the bottom curb and rollers." It is also the writer's idea that the sole provision for guiding and maintaining the stability of a holder will be the rollers on the outer lift working against guides in the tank, and only carried by short pieces or brackets to the height of 5 or 6 feet above the water-line.

In writing of the uncertainty respecting the value and effect of the stresses to be provided for, Mr. Webber says: "I have seen holders wrecked that should have been standing to this hour; and I know of holders still standing and doing service that ought, according to rule, to have been blown down fifty times over. They stand simply because they cannot help it, or because they have never been subjected to such destructive stresses as are supposed to be inevitable for such structures."

The writer then enters into an elaborate calculation in regard to the actual force of the wind on gasholders; prefacing his remarks by stating that, in view of experiments and observations by many celebrated engineers on this subject, "it will be fair to assume

that a pressure of 20 lbs. to the square foot is the greatest actual force that wind is likely to exert over the whole exposed side of a gasholder erected anywhere in the United Kingdom." As regards the difference in pressure in favour of a cylindrical surface over a vertical plane surface, he takes 50 per cent. of the area of vertical cross section as representing the actual equivalent plane exposed to the wind. Upon the question as to the manner in which the wind pressure is exerted, and how it is divided between the columns, &c., composing the guide-framing, Mr. Webber joins issue with the writer preceding him [M. Arson*]; claiming that there is no justification whatever for the assumption that wind pressure tends to push a gasholder *bodily along a horizontal plane*, as it is not a stable bulk, but an unstable body, and when pushed against will *capsize before it will slide*—that is to say, "the wind pressure on a gasholder is an overturning force." The reason of this is on account of the centre of gravity being so much above the centre of the figure. A gasholder is a cylindrical iron-covered vessel, without a bottom, required to float in water, the vessel being in unstable equilibrium; hence it tends to topple over as soon as the two centres cease to be maintained in a vertical line. Every holder must be so guided at all possible altitudes that the centre of gravity and the axis or centre of figure shall be always in a vertical line. If this condition is seriously disturbed, swift destruction of holder and framing must ensue.

Continuing, the writer says: "The steadiness of a gasholder depends far more upon the tightness of the bottom rollers than upon any other condition. It is the practice of good gasholder erectors to make the bottom rollers fit the tank-guides as tightly as they can be dropped into place. When this is done, the proper adjustment of the upper rollers will enable a holder to work without a tremor, however gusty the weather. . . . When the bottom rollers bear tightly all round, the overturning leverage of the top-heavy holder is constantly opposed by the leverage between the *leeward* top roller and the *windward* bottom roller; and as the distance from the latter to the centre of gravity is very much greater than the distance from the same centre to the top roller, its controlling effect is correspondingly greater. This demonstration of the part played by leverage, as distinguished from horizontal equable thrust, in the conditions of a holder's stability, concludes the part of this paper which deals with established principles."

In conclusion, and practically suggesting his ideas of improved construction in the matter under consideration, the writer says he would build on the tank wall a series of concrete or brick piers, about 6 feet above the water-line, 6 feet by 2 ft. 3 in. at the base, and tapering to smaller dimensions above. The strain of the holder is first taken by the tank guides, which are cast-iron boxes, 6 in. by 6 in., filled with concrete, and, of course, rigidly secured to the tank walls and piers.

Briefly stated, the plan of Mr. Webber is to secure the holder firmly at the bottom with radial and tangential rollers, placed in two rows, one row secured to the bottom curb, and the other to a secondary curb placed about 5 feet above the bottom curb—both curbs to be extra stiff and strong; the idea being that the holder shall be considered as "stepped" into a socket, and that socket holding the vessel with a grip strong enough to withstand the pressure of the wind, and yet loose enough to allow it to rise and fall freely.

Mr. Webber says: "It may be asked if the holder is strong enough to transmit all these strains to the point of support without taking some of the pressure off by means of external framing. To this it may be replied that if the holder is strong enough to withstand the strain at the top of the socket [that is, at the top of the short piers], where it is most severe, it must necessarily be able to carry them at other points, where they are less. So long as the holder preserves its true figure, it will transmit exterior strains to the ground as perfectly as would a surrounding framework; and it must always preserve its figure while the pressure of gas from within is in excess of that of the wind outside, even without the help of the vertical stays and the curbs. A wind pressure of 20 lbs. per square foot is only equal to a gas pressure of 38-10ths; so that most holders have an ample margin of internal force."

In the discussion on the paper Mr. Corbet Woodall said that, although they might not be disposed to adopt Mr. Webber's theories, they would all thank him for having given an admirable paper, and a healthy shock to anything that might be called stereotyped ideas on gasholder guiding and constructing generally. Gasholders must, it seemed to him, become different, more costly, and elaborate structures altogether if the scheme were to be adopted with a chance of success. He thought the cost of a holder built on Mr. Webber's plan (that is, stiff enough to stand the strains of wind pressure, with only short columns about 6 feet high, on the principle of a post "stepped" in a socket) would be very heavy—probably as great as one provided with external framing. In order to make the bottom rings of the rollers so rigid as to keep their form and resist the tendency to crush in (on the leeward side), so much metal must be used, in external curbs and otherwise, as would go far to dissipate the outside saving. Mr. George Livesey said that he was about to try trebling a double-lift holder without continuing the framing up to the third lift, and considered there was no danger in doing so if tangential and radial rollers were used for the two lower lifts. The upper lift would

See JOURNAL, Vol. XLIX., p. 631. | *Ibid.*, p. 722. ; *Ibid.*, p. 761.
§ *Ibid.*, p. 806. || *Ibid.*, Vol. L., p. 171.

* A translation of M. Arson's well-known *mémoire*, by Dr. Pole, F.R.S., will be found in the JOURNAL, Vol. XXIX., and in "King's Treatise on Coal Gas," Vol. II.

have its radial roller to guide it until the second lift was cupped; then it would go clear of the framing. He could not agree with Mr. Webber's plan, and did not think it safe. He had a feeling that there was some uncertain element in the question, which would bring a gasholder to grief if guided in that way. He did not see how the inner lift was to be guided until it was cupped. He believed that a three-lift holder could be safely guided by framing reaching only to the top of the outer lift; so that when fully inflated the stability of the holder would be dependent upon the top and bottom rollers of the third lift, which he really believed would be sufficient to safely support a gasholder properly constructed. It would certainly not be wise for any engineer to make an experiment of this kind unless perfectly certain it would be safe. After the discussion, Mr. Webber stated that he simply put forward a suggestion which had to be proved. This would dispose of a great deal of the criticism which had been offered. He further said that "the difference between Mr. Livesey and himself was only one of degree." He fully admitted that in this matter they must "proceed by steps."

The next article is by Mr. W. Gadd, C.E., of Manchester.* Speaking of wind pressure on holders, he says that investigations and experiments have led him to the conclusion that "average wind pressures are about the most misleading facts possible for the guidance of the constructive engineer, as it is the momentary or sudden gusts or pressures which really do damage to structures, and not the steady winds, even when these are of a very violent character." Mr. Gadd then suggests a method of guide-framing which he calls "opposite leverage carried below ground." This idea, not very clearly described, is an absurdity not worthy to be mentioned. In the following issue of the JOURNAL, Mr. Webber returns to the controversy, and becomes somewhat personal in his remarks concerning Mr. Gadd, whom he accuses of never having seen a gasholder built. Mr. Gadd, in his article, having spoken of "counterbalancing," Mr. Webber states that "counterbalancing went out when exhausters came in"—a rather wild statement for him to make. In reply to Mr. Webber, Mr. Gadd [in the following number] admits that he has never been engaged in gasholder building, but states that, "nevertheless, he has seen a goodly number, and finds that there are still in use a number of counterbalanced holders."

A new, and very sharp writer, under the *nom de plume* of "Theory and Practice," also enters the lists in the same issue, and criticizes Mr. Webber for his opinions in regard to tight-bottom rollers, which would be absolutely necessary to carry out Mr. W.'s ideas. He insists that gasholder work cannot be so nicely adjusted as to ensure perfect fitting contact between rollers and guides, to say nothing of their becoming loose by wear. On the subject of counterbalancing, he also takes Mr. Webber to task. "Scores of gasholders exist," he says, "with counterbalance-weights where exhausters are in use." Continuing, he says: "To my mind you do not want to force gas against a much heavier gasholder than is necessary to give the requisite pressure in the service-mains; otherwise you are wasting engine and exhauster power, and therefore increasing wear and tear and expense." And he adds: "If gasholders are constructed to stand the strains his [Mr. Webber's] mode of guiding would put upon them, the gas company's account for steam power will be nearly doubled, unless he employs counterbalance weights to his holders. . . . Mr. Webber's 6 feet guide-framing is a monstrosity." In the JOURNAL for Sept. 6, 1887, Mr. Webber answers his unknown critic; maintaining his opinion that holders can be, and are made with the bottom rollers nicely adjusted, and with steel pins working in good bearings, preventing wear and capable of adjustment. He also insists that counterbalanced holders, although still in use, are obsolete. "Theory and Practice," as the champion of Mr. Gadd, returns to the charge in the JOURNAL for Sept. 13. He reviews Mr. Webber's opinions on subjects that have been gone over before, but adds nothing of importance to the subject under discussion. Mr. Gadd also criticizes Mr. Webber in a letter in this number of the JOURNAL. Referring to Mr. W.'s remark that the bottom curb of a gasholder is perfectly rigid, he says: "Nothing is perfectly rigid, not even the great earth itself, which bends and bulges under the varying strains of the moon's attraction and its action on the mobile ocean." Continuing, he says: "At the present moment I am inclined to think it possible to devise a holder not only possessing no external guide-framing, but dispensing with any piers whatsoever, and having only one row of rollers at the bottom of the ring, yet forming a structure more stable than the one at present in use, although the rollers may be far from tight in practice." (This no doubt refers to Mr. Gadd's system of spiral guide-framing, an account of which was given in the *American Gaslight Journal* for Sept. 17, 1888.†) In regard to Mr. Webber's statement that counterbalancing is obsolete, Mr. G. D. Malam writes [in the same issue]: "An 80-feet three-lift holder which I designed two years ago has two of its lifts counterbalanced. The exhauster has thereby been relieved of 20 per cent. of unnecessary work."

The next two articles‡ are evidently from the pen of the writer of the original article. From his very lengthy demonstrations on the subject of centre of gravity, with pressure, &c., he draws the following conclusions:—(1) That gasholders cannot work at all without at least two tiers of rollers to each lift, thereby necessitating guide-framing. (2) That single-lift holders cannot work safely without sufficient depth of guide-framing. (3) That

unless the depth exceeds one-seventh of the diameter, much weight of material is necessitated. (4) That a telescopic gas-holder is even worse, unless the guide-framing exceeds one-seventh of the depth, owing to lever power. (5) Even without wind pressure, or weight of snow, the above is true, and much more so, with short guide-framing. (6) Under certain conditions, gasholders can be constructed without guide-framing reaching higher than the height of the outer lift; the conditions being that each lift must be rigid in itself, and unable to distort under the strains induced, that the guide-framing must also be rigid and unyielding, and that the holder must be free to rise and fall perfectly level. (7) The inner lift would not rack out of shape when the vertical stays are strong and well attached to strong curbs and sheeting; but, as an additional safeguard, diagonal ties may be introduced between the vertical stays, and so relieve the side sheeting from diagonal strain. (8) Gasholders can be constructed safely with the inner lift unsupported by external guide-framing after it has cupped, providing the guide-framing is carried to the height of the two outer lifts. (9) That it is neither safe nor advisable to make treble-lift holders with guide-framing to the outer lift only.

In the JOURNAL for July 31, 1888, is given an account of the completion of the gasholder at the Rotherhithe station of the South Metropolitan Gas Company; this holder having been changed from a two-lift to a three-lift, and erected without guide-framing beyond the height of the second section. Early in the discussion on this subject, Mr. Livesey stated his intention of making this experiment. Of course, this practical example and bold innovation on the old time methods is still in the experimental stage, and has yet to stand the test of the elements. The holder is 150 feet in diameter, with 25-feet lifts, standing in an iron tank only half sunk in the ground. It will thus be seen that the conditions were not favourable; and if the holder stands and works to the satisfaction of its builder, it will be all the more a success for its projector. The crown of the upper section was heavily trussed; the JOURNAL stating that the superfluous metal amounted to 80 tons. The paper also states that the columns were connected at the top and middle by lattice girders; and no mention is made of any change in this respect. This portion of the guide-framing it seems to the writer, will be the first to be dispensed with in the future. The JOURNAL further states that Mr. Livesey expressed himself as perfectly satisfied with the result, which practically marks a new era in gasholder construction. The article concludes as follows:—"It shows that monumental structures are not necessarily strong, and that massive Doric columns and heavy crown trussing are not enough, by themselves, to constitute a trustworthy holder. Regard for right principles is the only fountain of security in gasholder construction; and the most important principle of the art may be briefly summarized in the aphorism: 'Take care of the bottom, and the top will take care of itself.'"

The person writing under the *nom de plume* of "Theory and Practice," in the controversy, again comes to the front, in a very clear and concise letter to the JOURNAL for Aug. 21 last. Referring to the article on the successful issue of the Rotherhithe experiment, he says: "The writer of the article also infers that, because the top lift does not blow over when the top part of the guide-framing is done away with (as at Rotherhithe), it does not push at the top guides when the framing is carried to the full height, as usual; or, in other words, that the top roller-carriages never have any work to do. This clearly shows what false conclusions may be drawn from an experiment improperly understood. In the Rotherhithe gasholder, the total horizontal push of the wind, the resultant horizontal shear, the bending strain at the foot of the guide-framing are all the same, as if the framing reached the full height. The crippling or buckling strains are increased because the cups are not so well suited to resist distortion as the strutted top curb is, and therefore render but little assistance to the guide-framing. The great difference in the conditions is this: The bell of the gasholder itself is now called upon to act as a cantilever in its upper lift, which it is not required to do in the ordinary construction. It would undoubtedly push against the top of the guide-framing if there were any to push against; but as there is not, it has to take all the bending strains in itself, caused and created by abolishing the top framing."

[Here the article closes; the writer doubtless intending to devote his next communication to a consideration of Mr. Gadd's "spiral" system, as laid before the Manchester District Institution of Gas Engineers in August last, and to the enunciation of his own views on the subject under discussion—Ed. J. G. L.]

THE BRISTOL GAS COMPANY AND THE SLIDING SCALE.—As the result, doubtless, of the unsatisfactory answer received by the Bristol Gas Company to their application to the Sanitary Authority on the subject of the proposed adoption of the sliding scale by the Company, as recorded in the JOURNAL last week, the Directors have decided not to proceed any further in the matter.

THE REPORTED DISCOVERY OF PETROLEUM IN CHESHIRE.—According to statements which have lately been circulated, there is good reason for believing that no importance need be attached to the recent discovery of petroleum in a well at Anderton. The pump over the well, taken down when the petroleum was found, has now been put up again, and the well covered in. Any petroleum there was in the well has almost entirely disappeared,

AMERICAN GASLIGHT ASSOCIATION.

THE ANNUAL MEETING AT TORONTO.

As intimated in the JOURNAL a fortnight ago, the sixteenth annual meeting of this Association was held at Toronto on the 17th, 18th, and 19th inst.; and we understand that it was highly successful. From the programme of business we learn that the proceedings were formally opened on the first-named day by the President (Mr. T. Turner, of the Charleston Gas-Works); and after the minutes of the previous meeting and the applications for membership had been read, reports were presented from the Executive and Finance Committees, the Treasurer and Secretary (Mr. C. J. Russell Humphreys), and the Committees on Standard Meter Couplings and Badges. The President then delivered his Inaugural Address, which was well received. The election of officers and members and the reception of the report of the Executive Committee on Amendments to the Constitution completed the morning's work. In the afternoon, the reading of papers was commenced. The first was a communication from Mr. James Somerville, of Indianapolis, dealing with the "Daily Experience of a Gas Manager." Mr. Fred. Mayer, of Baltimore, followed, with a paper on the "Construction of Gasholders and Wrought-Iron or Steel Tanks above Ground;" and this was succeeded by one in which Mr. D. H. Geggie, of Quebec, related his experience in the distribution of gas under extremely low temperatures. On the 18th, the two papers down for reading were: "Coals for Gas Making, with Special Reference to Provincial Coals," by Mr. J. D. Perkins, of New York; and "Enriching Gas with Naphthalene," by Mr. A. Kitson, of Philadelphia. The remainder of the morning was occupied with the transaction of miscellaneous business, and the reception of reports of Committees. In the afternoon, papers by Mr. J. R. Smedberg, of Baltimore, and Mr. A. Q. Ross, of Cincinnati—on "Observations during Many Years' Experience in the Gas Business," and on "The Steam Stoker and Improved Charger"—were taken, and the contents of the "question-box" disposed of; after which the meeting adjourned. In the evening the usual banquet took place. On the following day, the Toronto Gas-Works were inspected in the morning; the afternoon being pleasantly occupied in driving round the city and suburbs. We hope to give some of the above-named papers next week.

ECONOMY OF ORDINARY COAL GAS AS A MOTIVE POWER.

In the recently issued volume of the Transactions of the Institution of Civil Engineers, there is a paper on "The Distribution of Hydraulic Power in London," by Mr. E. B. Ellington. The charge per horse power per hour by the London Hydraulic Power Supply Company was taken by the author at 4d.; and he thought that it would hardly be a profitable operation to supply public power under conditions similar to those which exist in London at less than 2d. per indicated horse power per hour, and that any idea of supplying it from a central source at rates much below this was chimerical. In the course of the discussion on the paper, the economy of the gas-engine as a motive power was alluded to. Mr. H. Davey said that some time ago he had mooted the question of supplying cheap illuminating gas for the distribution of power in Leeds. He was convinced that it would be almost, if not quite, the most economical system, if, as might be expected, a further development of the gas-engine was attainable. But taking this engine as it stood, he found that an ordinary gas-main would convey, in the form of common 18-candle gas, ten times the amount of power that would be transmitted by compressed air at 40 lbs. pressure. Messrs. Crossley stated that their engines gave about 1-horse power for 20 cubic feet of gas consumed per hour. In Leeds the cost of gas was 1s. 9d. per 1000 cubic feet; so that they could get 50 indicated horse power for 1s. 9d. This is equivalent to 0.42d. per indicated horse power per hour; or about one-fifth of the lowest practical charge as fixed by the author of the paper. Mr. Davey added that as compared with coal, and assuming a consumption of 8lbs. per indicated horse power per hour, the cost per ton, in order to furnish power at a similar rate, would have to be 8s. Mr. Dugald Clerk gave some figures showing the practical results of working an 8-horse power engine of his make in Birmingham, as follows:—

Engine Working at Full Power, and developing 10 brake horse power per week of 54 hours.

Gas, 13,200 cubic feet, at 2s. 6d. per 1000 . . .	£1 13 0
Water and oil	0 5 6
Attendance	0 3 0

Total £2 1 6

Engine Working at Half Nominal Power for a Similar Time.

Gas, 6300 cubic feet, at 2s. 6d. per 1000 . . .	£0 19 6
Water and oil	0 4 6
Attendance	0 3 0

Total £1 7 0

In the first case the engine required 240 cubic feet of gas per hour, and in the second 138 cubic feet; and it will be seen that the cost per brake horse power per hour was 0.92d. at full, and 1.5d. at half power. Mr. Clerk thought there was no chance of the hydraulic system approaching in economy anything like these figures. Mr. B. E. Thorpe referred to a gas-engine used for working an elevator at Mansion House Buildings, London. The cost of gas, at 2s. 9d. per 1000 cubic feet, was found to be 1s. 10.1d. per day; and the elevator made 385 trips per day. Allowing 1s. 5d. per day, or

about £20 per annum, for depreciation, &c., the cost would be 0.1d. per trip. With water power (water at 4s. per 1000 gallons), the cost would be 0.14d. per trip. The man who had to be on the premises looked after the engine; if he had to be employed for the elevator service only, it would be a question at once of using water power. These figures are sufficient to show that, wherever there is facility for fixing a gas-engine, and a workman can be spared to look after it, ordinary coal gas is a much cheaper source of power than any system worked from a central station. Of course there may be cases where the supply of power is only needed at rare intervals, or the demand is very small, where the fixing of a gas-engine would be objected to, or where the first cost of the engine would be an obstacle to its adoption.

INVERTED V. ORDINARY GAS-BURNERS.

With reference to the improved illuminating power and the economy in the consumption of gas ensured by the use of inverted gas-burners, Dr. Bunte, in the *Journal für Gasbeleuchtung*, has made a few observations. His experiments were conducted with the Weber photometer, which instrument not only measures the illuminating power of particular sources of light, but also the light produced by this source in different parts of a room or workshop. The decision upon the light obtained is so much the more important, as regards an appreciation of the illuminating power and the value of the burners employed, when it is borne in mind that the distribution of the light greatly depends upon the question of the employment of inverted burners or the ordinary Argand or batwing burners. Whilst with the former the light is chiefly thrown downwards, with the others there is a greater evenness in the distribution of the light upon all parts of the space illuminated. It is therefore necessary to establish by experiment the relation existing between the consumption of gas and the light obtained in the same place according to the type of burner employed. Although these observations cannot be applied except to each particular case (inasmuch as the reflection of the walls, the decorations, &c., produce considerable effect), still it is of very great importance to make these inquiries, and determine the relation existing between the quantity of gas consumed and the light obtained. As an instance of this, in the amphitheatre of the Higher Technical School of Carlsruhe, until the commencement of the last winter quarter, the lighting was arranged in such a manner that 21 Argand burners were employed; whilst behind a reflector there was a row of seven "slit" burners specially prepared for lighting a board at the lower end of the room. This light was found insufficient, especially for the purpose of distinguishing with precision objects placed upon the board for the illustration of lectures, &c. With the view of remedying this inconvenience, the authorities wished to adopt electricity; but this project had to be abandoned, and they were forced to employ gas lighting—using the Siemens regenerative lamps for the purpose. Six burners were fixed, with the old Argand burners remaining; four of the former being placed in a row above the stalls, while two with reflectors served to increase the lighting of the board. Since the place had previously been lighted by means of the old form of burner, and now with the Siemens system, it was easy to make a comparison between the quantity of gas consumed and the respective lighting power obtained. To measure the quantity of the gas employed in the amphitheatre, a meter was fixed on the supply-pipe of each of the two systems. On the 28th and 30th of January of the present year, parallel tests were made, so that the room was lighted for one hour by the old, and another hour by the new arrangement, when the following results were obtained:—With the Argand or batwing burners, the consumption of gas was 5.018 cubic metres per hour, and that with the Siemens burner 2.633 cubic metres; whilst the illuminating power was observed in twelve different directions in the case of the Siemens, and in ten with the old burners. The result obtained by the employment of the Siemens burner was a great increase of light; being nearly double that previously produced. With regard to economy in the consumption, the Siemens burners consumed upwards of 52 per cent. less gas, and yielded double the illumination of the others. It will thus be seen that the inverted flame burners approach as near perfection as possible, and that gas lighting can still compete with all other methods of illumination.

THE VENTILATION OF GAS-LIGHTED BUILDINGS.

In a recent number of the *Journal für Gasbeleuchtung*, a communication appeared by Herr S. Elster, of Berlin, in which he stated that the question of the ventilation of places lighted by gas had been a subject of consideration for three or four years by the Berlin Society of Gas Engineers, and that he had requested Herr Oechelhaeuser to make the necessary experiments, and to indicate the best means of realizing this much-desired object. He added that they had obtained outside assistance; and their researches upon the question had produced more than they had anticipated, for they did not expect to include in them so difficult a question as the radiation and conductivity of heat—their only wish being, as far as possible, to solve the great problem of effecting ventilation by means of gas illumination. Herr Elster's remarks were as follows:—

Last year I went to London, furnished with a recommendation from several architects of our city, in order to personally inspect the installations which had been made for obtaining ventilation by gas lighting. The best building fitted up at present, as far as regards ventilation by gas lighting, is the Examination Hall of

the College of Physicians, situated on the Victoria Embankment. This building includes a central hall, measuring 100 feet long by 16 feet wide. It has two storeys; and on the right and left there are two cross-wings, each measuring 60 feet by 24 feet—the one on the right being intended for anatomy and physiology, and the one on the left for chemistry. These wings are connected to the main building by means of lifts; and everything has been so arranged as to allow the work carried on to be done in the very best possible way so far as regards health—especially having in view the nature of the substances, subjected to dangerous fermentation, there exposed. On examination, it was found that the central building is lighted by twelve No. 2 Wenham lamps, and each of the side-wings by three No. 3 lamps. A certain number of chimneys are necessary, in order that the products of combustion of each burner may be conveyed outside the building. For this purpose earthenware pipes are employed, of 4 and 6 inches diameter, which are not laid in the ordinary way, but are placed in the walls constructed to receive them. It is said that the expense of laying the 60 pipes is no more than 1 per cent. of the cost of the building, which is about £5000. I have again to point out to our German architects, who state that the pipes for taking away the hot air should be at a distance of 18 inches from all woodwork, that this figure is admitted as correct—that the pipe is always placed at this distance from the floor. Upon examination, it is found that the windows are grouped in pairs, and that underneath two iron girders are placed, between which pass the pipes for conducting the air for combustion and for carrying away the vitiated air. These girders or joists are covered underneath, and form a kind of ceiling case. In this way it is possible to obtain a space of 18 inches between the pipes and the woodwork. The vertical earthenware pipes are connected by means of bends to the horizontal pipes, and are fitted to the walls in such a way that it is possible that the movement of the ordinary air in a pipe 6 inches in diameter may be produced by the displacement of the gas in two pipes 4 inches in diameter placed on either side, which convey the products of combustion beyond the roof. Above this may be seen, emerging one after another, the covered pipes, which are for driving the air upwards, and for actuating the ascending current. Inside this building, on the ground floor, the Steward's offices, &c., are situated; and nothing appertaining to either the ventilation or the heating of the place is allowed to go on without the authority of Drs. Stone and Percy. In Germany, we have comptrollers of gymnasiums, &c.; but we have no inspectors or comptrollers of private dwellings. There is an example for us to follow in this Institution; for it is on this that the satisfactory condition of the inside of the building rests with regard to health.

Herr Elster concluded by saying that what interferes with the development of ventilation in Germany at present is the obligation of always having the pipes for conducting away the hot air fixed at a distance of 18 inches from woodwork; whereas in England they are often satisfied with packing the pipes in silicate cotton, which is found to be quite sufficient protection.

Register of Patents.

AUTOMATICALLY LIGHTING AND EXTINGUISHING GAS-LAMPS.—Schiller, J. R., and Meyer, C., of Zurich. No. 14,808; Oct. 31, 1887. [8d.] This is an improvement on the patentees' previous similar invention—No. 6400 of 1887 (see JOURNAL for June 12 last, p. 1052).

Fig. 1 is a front view of the apparatus; fig. 2, a top view; fig. 3, a side view; and fig. 4, a plan of the connection of the lamps carrying the apparatus with the central station.

The principle of the apparatus is essentially the same as that described in the earlier patent. One, two, or more electro-magnets act upon an oscillating or swinging armature when an electric current is passed, in such manner as to cause the armature to operate a lever, by means of which the gas-cock is either opened or closed. A wire or wires leading to the gas-burner produce sparks as the current passes through them, whereby the gas escaping from the burner, after the cock has been opened as indicated, is ignited. The apparatus for this purpose consists of two electro-magnetic spools F, which, with their armature, are enclosed in a gas-tight box. The bottom of this box carries on its under surface a nipple or sleeve C, by means of which the box is attached to

the gas-pipe. Inside the sleeve is an inverted cone, the hole through which forms a passage for the gas passing into the box. The object of this device is to prevent impurities (such as tar), carried along by the gas, from entering the box and deranging the apparatus. Induction coils, which have cores of thin soft iron wire, are attached to the bottom; these consisting of several layers of thick copper wire, upon which thinner copper wire is wound. One end of the thick wire of one spool is connected to one end of the thick wire of the other spool; the other ends of these thick wires passing through the bottom, from which they are separated by an insulating plate H. One end of the thin copper wire of one spool is secured to one end of the thin wire of the other spool; the third end is soldered to the bottom of one of the spools; while the fourth end passes (well insulated) through the bottom of the box, from whence it runs along the outside to the gas-burner. A permanent magnet K swings in front of the spools. During the passage of an electric current through the primary coils of the spools, the iron bundles will show homonymous poles, in consequence of which one end of the permanent oscillating magnet will be attracted, while the other is repelled. The magnet carries a bent arm, the free end of which hangs between two regulating nuts, collars, or lugs D, which are adjustably fastened upon the stem V. This stem slides in two guides or bearings, and is at one end provided with a cone, which fits into the seat of a valve, from which a pipe A leads through the top of the box to the burner. The main current passes from the battery X, through the commutator W, and then through each of the lamps L—that is through the primary coils of the spools of each apparatus to the electrode W¹; and from here the current passes through the earth to the electrode W², through the commutator W, and back again to its source X. The induction current is generated only in the secondary coils of the spools, and produces the spark for igniting the gas. The commutator Y, inserted in the line, serves for either sending the current uninterrupted direct through the line with the lamps L, or for sending it first through the contact breaker Z, and then through the line, whereby the current is made intermittent. The operation of igniting the gas-flame is performed as follows:—The current when closed passes into the interrupter Z; and from there again through the line. In consequence of the interruption of the current at the central station, the current produces in the spools of each apparatus an induction current, which passes to the burner, where on opposite sides a wire is soldered. The sparks produced between the two wires cause the gas escaping from the burner to be ignited; and the gas having been ignited, the current is not further continued. For extinguishing the flames, the commutator W is reversed, and the current closed. The magnet K is now attracted to the other side; and thus closes the valve in the manner already described.

DISTILLATION OF AMMONIACAL FLUIDS.—Davis, G. E., of Manchester. No. 15,540; Nov. 14, 1887. [8d.]

In stills for the evolution of ammonia gas or of carbonate of or sulphide of ammonium, from any of their solutions, it has (says the patentee) been the custom either (1) to drive off the volatile substances by means of a jet of steam blowing direct into the liquor contained in a boiler of the usual pattern; (2) to heat the liquid by means of direct fire; (3) to pass the steam and vapours up a tower or column filled with bricks or boards, down which the ammoniacal liquid is made

to pass; or (4) to cause the liquid to run down a column containing shelves pierced with large central apertures covered with caps serrated round their lower edges, through which the vapours are made to pass. In all these methods the ammoniacal vapours are not so finely divided as they might be in order to get the utmost possible work out of a given size of still; and the present invention relates to the construction of distilling apparatus whereby a much larger quantity of ammoniacal liquor can be distilled in a given space than heretofore, and with ordinary care can never become choked with tar.

The still is constructed of a metal cylinder with a number of trays. Each tray is fitted with an overflow-pipe D, dipping into a shallow well E; and these trays are perforated with a number of small holes, through which the vapours pass when the still is at work. About one hole, three-sixteenths inch in diameter, in every square inch of tray is the number found to be sufficient. Any volatile ammonia compound present in the solution undergoing distillation is driven off in the upper portion of the still; and the partly freed liquor, passing through the pipe G into the lime vessel K, becomes mixed with the lime or soda introduced through the pipe M. From K the liquor finds its way again into the column through the pipe H; and in passing down the column over the perforated trays, becomes denuded of its fixed ammonia, finding egress from the column at the outlet I, by means of one or more U-tubes, which allow of the escape of liquor and still retain the steam.

In practice, the liquor to be distilled is run into the still or column

--preferably having first been heated by the waste steam—by means of the smaller pipe on the top of the still; and when steam is admitted by the pipe N, the liquor will form a layer on each tray, of a depth corresponding with the top of the overflow-pipes D, by means of which it runs from tray to tray until it finally reaches the point I, almost entirely freed from its ammonia. The steam and other vapours pass through the holes in the trays, and find their way through the liquor standing on each into the spaces J above; and so on from tray to tray until they finally escape, highly charged with ammonia, by the large pipe upon the top of the column. When the steam is turned off, the liquor will fall from tray to tray; and any tar which may have settled thereon, finds its way by the pipe G into the lime-box K, whence it is removed (together with the refuse lime) by means of the tap L, or by the manhole with which this box is provided.

This form of apparatus answers best when used for the distillation of the quantity of liquor which it is calculated to work. When the quantity of liquor to be distilled is very irregular, it is preferred to make the perforations in the top of a flat cylindrical cap A in fig. 2. At B is shown one of these caps *in situ*; while the plan C exhibits the method of perforation. These perforated caps and trays may then replace the simple perforated trays in fig. 1.

MANUFACTURING ILLUMINATING GAS FROM COAL.—Dinsmore, J. H. R., of Liverpool. No. 15,852; Nov. 18, 1887. [8d.]

This invention relates to the manufacture of illuminating gas from coal in closed vessels or retorts; but more particularly to those processes of manufacturing illuminating gas in which it has been proposed to render permanent practically all the heavy or tarry vapours as well as the light volatile products given off from coal by distillation and useful for the production of light and heat. To obtain this result, double or multiple retorts have been proposed, in which the gas distilled in one retort was to pass through a second or third retort; such retorts being arranged and constructed in various ways and forms. The present invention has for its object chiefly to effect these results, and at the same time to avoid the deposition of carbon or pitch in the ascension-pipes of the retorts, or at any parts of the retorts themselves that cannot be readily removed; and in this way escape the disadvantages attending or incident to the ordinary and other processes of gas manufacture heretofore proposed.

The drawing illustrates a sectional elevation of apparatus according to this invention having a plurality of cooled surfaces.

A is a retort in which the coal is distilled in the usual manner; and B are ducts of any suitable material, arranged at an incline, and through which the gas passes after leaving the retort. D are cooled passages interposed in the ducts B, each having a jacket and a door E. The exit or ascension pipe and the mouth of the duct are also cooled and provided with a jacket. The mouth and the passages D of the ducts B are provided with inlet and outlet pipes F, through which water or cold air is led to and from the space between the jacket and the metal of the mouth or passages. The temperature to which it is preferred to heat the ducts and retorts in all cases is a clear cherry red colour. The example illustrated is suitable for those kinds of coal from which the volume of heavy and tarry vapours is large. The ducts B are smaller than the retort A; the proportion shown being one from which good results may be obtained. The setting or support of the retort A consists of a front wall C and pedestal C'.

When set in a bench in the usual manner, the retorts subject to the greatest heat would be shielded by brickwork or slabs of fire-brick throughout their length, or at intervals, as in ordinary practice. Any required number of retorts may be set in a bench in the usual way; but care must be taken that they are arranged in such a manner that the temperature of all shall be about equal.

It will be observed that each retort with its duct or ducts is an independent complete gas-making apparatus; having no valves, and comprising a plain receptacle and open ducts. Direct access can be had to the retort A and ducts B from the doors; and through these door apertures, the whole of the interior can be scraped and cleaned, and any deposited carbon or other matter adhering to the interior surfaces of them can be removed.

The mode of manufacturing gas is thus described by the patentee: The coal is placed in the retort A, and distilled by heat in the usual way. The gas evolved from the coal leaves the retort and passes through the heated duct B. When the gas comes in contact with, or under the influence of the cooled passages D, that portion of the tar or tarry vapour existing in the gas in a non-permanent state is condensed and arrested; and the tar being in a fluid state will, owing to the inclination of the ducts, flow backwards down them. As soon as the tar comes in contact with the hot surfaces of the ducts B, it is converted into gas; and such gas will, in passing through the successive heated ducts, be rendered permanent. In cases where the coal is being distilled in the retorts shown in the figure, having a plurality of cooled surfaces and heated ducts, an extended and repeated cooling and heating effect is produced—i.e., the gas coming from the retorts A is subjected to heat three times, and a chilling influence three times; hence the gas resulting from the evaporation of the tar condensed in the first cooled passage D flows down the lowest duct B, and is so converted into gas, but instead of going straight to the ascension-pipe, it is subjected to the heat of the

remaining two ducts, and is so rendered permanent. In like manner, the tar in the gas not condensed by the first cooled passage D or still in a non-permanent condition, will be condensed by the following one, and is treated in a like manner.

GAS LIGHTING AND VENTILATION.

SIR,—I was glad to see the statement in the JOURNAL for the 16th inst., that "at the new establishment of Messrs. W. Sugg and Co., Limited, Westminster, there is now on view an interesting system of lighting combined with ventilation, which should be seen by all who wish to keep abreast of modern progress in the utilization of gas." Well, without troubling myself about any of Mr. Richard Swiveller's notions, I went to the establishment named; and there I was delighted to see a mode of lighting by gas which is as free from the charge of taking oxygen from the air of the room so lighted, or of adding thereto any deleterious gas or vapour, as any electric incandescent system of the same or any other power. Now this, I think, will be a "staggerer" to Mr. Richard Swiveller, if he is an electrician; and if not to him, it will be to many who are always telling the public that gas *cannot* be used as an illuminant without offence. As for me, I have been firmer on my legs ever since I saw it; and hope the same is the case with others.

Oct. 25, 1888.

W. MANN.

PIPE EXTRACTORS.

SIR,—As to Mr. Helps's patent pipe extractor, I should like to ask your numerous readers engaged in main-laying if they ever used any other scheme than the clip and screw, or screws and jacks, for pushing off pipes? Of course, no one would think of breaking out, cutting off, or melting out a large number of pipes; but iron being so cheap at present, a few small-size pipes cut off or broken is not a matter of consequence—although they can be pushed off much quicker with a hydraulic jack. Will your correspondent, Mr. May, explain what size and kind of joint in a gas-main he is unable to push off with two screws, if the joint refuses to give? Of course there is no patent to stop us from lifting the end of the pipe, and dropping or jarring it, as we have done for the last half century. What would Mr. May think of erectors taking down an engine, and breaking or cutting all the steam and feed pipes, instead of using a screw or screws, or jacks?

Oct. 26, 1888.

PIPE LAYER.

WATER BY MEASURE.

SIR,—I shall be glad if you will allow me space for a few remarks on a passage in the article which appeared under the above heading in the last issue of the JOURNAL.

The author, in referring (on p. 717) to my paper, "Notes on Water Supply, with Special Reference to Villages and Country Mansions," read in January last before the Surveyors' Institution, said: "It is stated that less than 3 gallons per head per day is an ample supply for cottages, while most water-works engineers have placed it at 20 gallons and even 30 gallons per head." If the author will kindly refer to my paper, he will find that what I stated was: "The quantity required for cottages has been estimated by various authorities at 2 and 2½ gallons per head per day;" and I quote the source of this information. I did not state, nor did I intend to show, that it was an ample supply. It was simply evidence of the quantity actually used in country cottages; and if the author will also refer to Dr. Pole's lecture on "Water Supply," delivered before the Institution of Civil Engineers in February, 1885 (see JOURNAL, Vol. XLV., p. 440), he will, I think, see that probably it is not far from the truth. Dr. Pole says, in reference to supplies to towns: "The quantity actually required for domestic consumption, including a fair allowance for general household purposes, for water-closets, and for ordinary ablutions, is probably not more than 10 gallons per head per diem." In country cottages there are no water-closets; and in other ways less water is used. So that 10 gallons per head in such cases is very much reduced. At the same time, if water were laid on under pressure to such cottages, I should by no means advocate limiting it to the small quantities now used. I think that, in speaking of 20 and even 30 gallons per head, the author must have meant the average supply of towns. But even then I consider the estimate of 30 gallons too high; for Dr. Pole goes on to say: "But, in addition to domestic consumption, supplies have to be provided for gardens, stables, manufactories, and trade purposes of many kinds, baths, and wash-houses, public fountains, watering streets, flushing sewers, and extinguishing fires. The quantity for these purposes will vary considerably—say, from 5 to 10 gallons per head per diem." Here we have, with the 10 gallons for domestic consumption, from 15 to 20 gallons per head; and it has been shown, in more than one case, that, by a careful system of inspection, these quantities are sufficient—the surplus simply running to waste.

I certainly agree with the author entirely in objecting to a supply of water by meter.

Oct. 24, 1888.

RICHARD F. GRANTHAM.

SIR.—In the article on "Water and Sanitary Affairs" in the JOURNAL for the 9th inst., the following passage appeared as the conclusion of it:—"That houses should be left without proper cisterns to receive and store the water, is certainly a monstrous perversion of what is intended

by the constant supply. If such an arrangement receives the sanction of the law, the consumer had far better revert to a supply on the intermittent system, with its accompanying reserve under his own control. Without this provision, the outbreak of a fire, or the execution of necessary repairs, may occasion serious inconvenience, by the sudden cessation of a supply otherwise constant, and relied upon as such." Your correspondent "Meter," writing in the last number of the JOURNAL, said: "A water-meter working under pressure is a different thing to a gas-meter." The italics are mine, and they are for the purpose of asking whether your correspondent has never heard of water-meters which do not work "under pressure." Cisterns being a necessity, why ought not low pressure water-meters, placed over the cisterns, to be used? Oct. 26, 1888. TRUE MEASURE.

THE EDINBURGH AND LEITH GAS-WORKS PURCHASE.—Our Edinburgh Correspondent, writing last Saturday, says: "With your permission I would like to say a word or two with reference to Mr. Romans's letter which appeared in this week's JOURNAL. I think it bears out my remark of Oct. 16, that he is a little impetuous. I beg to assure him that I made no mistake about his attitude upon the general question of transferring the gas supply to the Corporations. What I said was he 'strongly opposed last year the transfer of the Edinburgh works.' That certainly was Mr. Romans's position. He considered the bargain was bad, and did all he could to get it overthrown. Further down in his letter he speaks of my applauding a 'tinkering method.' Here again I must reproduce my words, which were: 'Meantime I am not convinced that it is not the best policy to expend a moderate sum upon the improvement of the Edinburgh works.' This, I should say, is very faint applause. It is not my object to discuss Mr. Romans's views on the general question; but in one particular I may say I am in thorough accord with him. That is when he speaks of 'the recent schemes.' My opinion all through the negotiation was that, on the part of the Corporations, there was too much scheming; and that, had a more straightforward policy been adopted, the terms of transfer need not have been so high nor so difficult to fix."

ROTHERFIELD AND CROWBOROUGH GAS COMPANY, LIMITED.—This Company was registered last week, with a capital of £6000, in £5 shares, to acquire land at Crowborough, or its vicinity, in the county of Sussex, for the construction of works for supplying Rotherfield, Crowborough, and the neighbourhood with gas, and the carrying on of the usual business of a gas company.

GEORGETOWN (BRITISH GUIANA) GAS COMPANY, LIMITED.—The Directors of this Company, in their report to be presented at the ordinary meeting of the Company next Tuesday, state that the profit for the half year ending June 30 last amounted to £1404 7s., which, added to the balance brought from the previous accounts, makes £3147 16s. After paying the dividends to Dec. 31, 1887, and the interest on debentures to June 30 last, there remains an available balance of £1852 18s., out of which they recommend the declaration of a dividend for the half year on the preference share capital at the rate of 8 per cent. per annum, and on the ordinary share capital at the rate of 7 per cent. per annum, both less income-tax (except upon those dividends payable to the local shareholders), which will leave a sum of £685 10s. to be carried forward to the next half-year's accounts.

THE PRICE OF GAS IN THE MANCHESTER OUT-DISTRICTS.—At the meeting of the Newton Heath Local Board last Thursday, a circular letter was read from the Gorton Local Board with regard to the charges made by the Manchester Corporation for the supply of gas to the out-townships, and the Chairman (Mr. J. M. Elliott) moved a resolution to the effect that, as the Manchester Gas Committee had shown, by their published accounts for the last financial year, that they had made a gross profit of £106,072 9s. 3d., equal to 25.49 per cent. (exclusive of lighting the city lamps), of which amount £26,452 had been contributed by the out-townships, the time had arrived when the price of 3s. 2d. per 1000 cubic feet now charged to consumers beyond the city should be considerably reduced, and that the various urban and rural sanitary authorities should appoint a deputation to wait upon the Committee to urge a reduction of at least 6d. per 1000 cubic feet. The motion was agreed to.

THE NORTHERN COAL TRADE.—There is considerable excitement in the coal trade of the North of England, in consequence of the stoppage of labour in a large proportion of the collieries of Yorkshire; and for several classes of coal there has been an advance of some moment in price. Steam coal has naturally gone up most; and within the past week it may be said that the rise in the general quotations was to the extent of 1s. 6d. per ton, whilst in several instances there have been considerably higher prices paid, and coal is very difficult to get. At present about 10s. per ton is the general quotation for best steam coal. Gas coal is also dearer, but from another cause. It is due rather to the growth in the normal consumption of this class of coal, and to the fact that the summer did not allow such a laying in of stocks as had been anticipated. Many of the gas-coal producing collieries are backward in their contracts; and it is generally stated that one large colliery is 20,000 tons in arrear with its deliveries. This scarcity of gas coal will be probably more felt as the winter advances; and already the price has been further put up for coal sold without contract—7s. 6d. being the current figure now. The general tendency of the coal market is towards increased scarcity and higher prices.

THE GAS QUESTION AT RASTRICK.—Last Wednesday evening a public meeting, called by the Rastrick Property Owners and Gas Consumers' Association, was held at Rastrick, to further consider the question of the gas supply of the district. Mr. H. Sugden presided, and severely criticized the report made to the Wakefield Quarter Sessions by Mr. J. W. Close, of Leeds, the Accountant appointed by the Court to examine the accounts of the Gas Company, as given in the JOURNAL last week. He said, however, that the report had proved every charge the consumers had made against the Company; and he contended that the £223 which Mr. Close stated in his report to have been spent in wines and cigars by the Directors ought to be returned by those who had consumed them in addition to receiving their fees as Directors. He should now be glad for the whole thing to settle down; and he hoped the consumers and the Company would be able to work together in the future, so that gas would be supplied at as cheap a rate as possible. Mr. Storey, the Solicitor for the consumers in the recent legal proceedings, addressed the meeting at great length. He gave an exhaustive *résumé* of the whole of the case, and severely censured several of the actions of the Directors of the Company. The following resolution was unanimously passed:—"After hearing the report of the Accountant, this meeting considers it highly necessary to re-elect the present Committee, and resolves that any balance remaining after all accounts have been paid remain in the bank."

Legal Intelligence.

HIGH COURT OF JUSTICE—CHANCERY DIVISION.

THURSDAY, OCT. 26.

(Before Mr. Justice STIRLING.)

LEWIS v. WESTON-SUPER-MARE LOCAL BOARD OF HEALTH.

This case, which was of some importance to local authorities, was heard during the last sittings, when his Lordship reserved his judgment. It was a motion to restrain the defendants, who are the Urban Sanitary Authority for the district of Weston-super-Mare, from carrying a water-main through certain freehold lands belonging to the plaintiff, and forming part of the garden of a house at Weston-super-Mare. The defendants had, under the powers of the Public Health Act, 1875, undertaken to provide their district with a supply of water, and for this purpose had constructed on their lands, adjoining those of the plaintiff, a reservoir, from which they desired to carry a main to a point on the other side of the plaintiff's property. Previously to March, 1888, negotiations had taken place between the plaintiff and the defendants for the purchase by the latter of a strip of the plaintiff's land for the purpose of laying the main in question; but these had not resulted in any binding agreement between the parties. On March 21, 1888, a report was made to the defendants by a Mr. Arthur Powell, a gentleman in their service, to the effect that it was desirable that the main should be laid through Mr. Lewis's land, and recommending that the necessary notice should be given to him forthwith. The report was signed "Your Surveyor, Arthur Powell;" and the question turned upon the right of Mr. Powell to use this title, and consequently upon the value of the report for the defendants' purposes under the Public Health Act. It appeared that Mr. Powell, who is a civil engineer, had been appointed in November, 1887, as assistant to the then Surveyor, on whose death, in the following month, he was promoted to the office, pending the selection of a successor. Mr. Powell's engagement under this resolution was determined on March 25, 1888 (four days after the date of the report), when a Mr. Collins was appointed Surveyor. The report of the 21st of March was taken into consideration by the Board, and adopted on the 11th of April last, after which notices were served on the plaintiff. Some correspondence ensued between the parties; and the defendants threatened to apply for a Magistrate's order under section 305 of the Public Health Act. This, however, was not done; and the plaintiff, finding that the defendants were carrying their pipes up to his land, on the 16th of June applied for and obtained an *ex parte* injunction, which was afterwards continued on notice; and the question now before the Court was whether this injunction ought to be continued to the trial of the action or further order.

Mr. BUCKLEY, Q.C., and Mr. HALDANE appeared for the plaintiff; Mr. GRAHAM HASTINGS, Q.C., and Mr. E. FORD for the defendants.

Justice STIRLING to-day delivered an exhaustive judgment. He said the defendants claimed the power to carry their mains through the plaintiff's land under sections 51, 54, and 16 of the Public Health Act. Section 54 provided that "when a local authority supply water within their district, they shall have the same powers and be subject to the same restrictions for carrying water-mains within or without their district as they have and are subject to for carrying sewers within or without their district respectively by the law for the time being in force;" and section 16 provided that "any local authority may carry any sewer, . . . after giving reasonable notice in writing to the owner or occupier (if on the report of the surveyor it appears necessary) into, through, or under any lands whatsoever within their district." The injunction was claimed on two grounds: (1) It was said that it was not and did not appear by the report of the 21st of March, 1888, to be "necessary" to carry the main through the plaintiff's lands; and (2) it was contended that Mr. Powell, by whom the report was made, was not "the surveyor" within the meaning of section 16 of the Act. Both these points raised questions on the construction of the Act; and his Lordship proceeded to deal with them at length. Having cited a number of authorities bearing upon the case, he considered the scope of the word "necessary" in the above-quoted section. He said it might well mean "necessary for the efficient discharge of the duty in the way which is most for the public interest." It was the duty of the surveyor to take all the circumstances of the case into consideration, and come to a conclusion as to the best course to be pursued, and to report accordingly—saying what was necessary to be done in order to carry into effect the scheme which commended itself to his judgment. If the Court found that the surveyor had exercised his judgment, and come to a conclusion in good faith, his Lordship apprehended that it ought not to interfere, although other courses by which the necessity for entering upon private lands might be avoided might be pointed out, and might be admitted to be practicable; and even although engineers of greater eminence than the surveyor might come forward and say that they would themselves have reported in favour of the adoption of one of the alternative courses. The second objection of the plaintiff had still to be considered. The defendants had power to carry their mains through the plaintiff's land only "if on the report of the surveyor it appears necessary." Who was "the surveyor" referred to? His Lordship then read sections 4, 189, and 190 of the Public Health Act, and said that, in his opinion, "the surveyor" mentioned in section 16 was the fit and proper person duly appointed under section 189, and no other—not even an engineer of the greatest eminence whom the authority might think fit to consult. Was Mr. Powell such a person? In his Lordship's opinion he was not. The Board had never come to the conclusion that he was a fit and proper person to be their surveyor within the meaning of section 189. All that they had determined was that he was competent to be assistant to their surveyor, and to discharge such of the duties as were necessary or proper to be discharged during a vacancy in the office of surveyor. He was, in fact, in the language of the Act, "an officer or servant, necessary or proper for the efficient execution of the Act," but not "the surveyor." It was said that the present surveyor, who was admitted to have been duly elected, and to be "the surveyor," had made an affidavit, in which he took the same view and approved of the report of Mr. Powell. His Lordship thought, however, that this was not material for the present purpose. The defendants were seeking to avail themselves of a power conferred on them by statute in derogation of the plaintiff's rights; and, so doing, they must follow strictly the terms of the power. The existence of a report of "the surveyor" by which the acts contemplated by them appeared to be necessary was, in his Lordship's opinion, a condition precedent to the doing of those acts; and as the report of the 21st of March, on which the whole of their proceedings were founded, was not the report of "the surveyor," he thought the plaintiff was entitled to an injunction until the trial of the action or further order.

THE Local Government Board have sanctioned a loan of £6000 by the Basford Rural Sanitary Authority, for works of water supply for the parish of Kirkby-in-Ashfield.

Miscellaneous News.

MR. ELLIS LEVER AND THE SALFORD CORPORATION GAS UNDERTAKING.

At the Meeting of the Salford Town Council to be held to-morrow, the attention of the members will be again specially directed to matters seriously affecting the gas undertaking of the Corporation. The *agenda* paper sets forth that the Mayor (Mr. Alderman A. L. Dickens) will submit a communication "with reference to the action of the Consulting Committee in a certain matter in the case of Samuel Hunter;" that the Council will also receive correspondence between the Mayor and Mr. Ellis Lever, "in respect of the resolution of the last meeting of the Council [*ante*, p. 645] as to the appointment of a Committee to consider certain statements made by Mr. Lever in the public press on gas matters;" and that Mr. Phillips will move that this resolution be rescinded so far as it relates to the appointment of a Committee, and that in lieu thereof the Council consent to Mr. Lever's proposal "that he shall nominate two members of the Council, who, being so nominated, shall themselves appoint a third, to whom he will disclose evidence of such frauds, and that the said members so selected shall be appointed to form themselves into a Sub-Committee to receive such evidence, and to report thereon to the Council." It may therefore be expected that the proceedings on the occasion will be lively. In view of the great interest, for the gas industry generally, which attaches to the charges made by Mr. Ellis Lever in connection with the Salford gas undertaking, it may not be out of place to reproduce certain portions of some letters which have lately appeared on the subject in the local press.

Mr. Lever's first communication—in which he offered, provided the Corporation would allow him to nominate two persons, with power in them to name a third, for the purpose, to show the Council, within 14 days, how the ratepayers were being "defrauded" in regard to their gas undertaking—was given in the *JOURNAL* for the 9th inst., in conjunction with the proceedings of the Council thereon. The result, it will be remembered, was the appointment of a Committee to hear what Mr. Lever had to say on the matters specially referred to in his letter. This Committee, as stated in the *JOURNAL* last week, Mr. Lever declined to meet, on the ground that they were all either ordinary or *ex-officio* members of the Gas Committee, whose conduct, it was to be presumed, he would impugn. His action called forth a letter from Mr. F. S. Phillips, one of the Committee, expressing regret thereat. He said: "I regret it, because I can see no good in continuing the present state of matters, making allegations and not bringing about an issue. I regret it also because a body of men constituting the present Gas Committee, who have done everything possible for the interests committed to their charge, are branded in the public mind as knowing or taking part in or permitting fraud; and I say that it is unjust to place this imputation upon us and refuse to let the matter be cleared up. I do not hesitate to say that the present Gas Committee has merited very different treatment." He suggested that Mr. Lever and the Corporation should both agree to accept a Committee of the Council to be nominated by an independent person—Mr. Oliver Heywood, the High Sheriff, being mentioned. The next day Mr. Snape followed with a letter, pointing out that the new Gas Committee had not been in office twelve months; and that the new Manager commenced his duties only a little more than six months ago. Since then, he said, the Committee and Manager had been working almost night and day, getting the works into as good condition as possible before the winter came on. Many improvements were in contemplation, but it would take months to execute them; and it would be another two years before a fair estimate of the work of the new Committee could be made. He therefore appealed to Mr. Lever and to the general public to suspend their judgment, and grant the Committee fair play. As to the objection raised to the Sub-Committee, Mr. Snape said: "The Council simply objected to Mr. Lever nominating his own judge and jury. They want an impartial tribunal. Will Mr. Lever accept a Committee composed of two members nominated by himself and two members nominated by the Council, with the Mayor for Chairman? If so, I will help him to get it." Mr. Snape proceeded to defend himself from a charge made against him by Mr. Lever of having "neglected his duty" because he did not act on certain information given to him by Mr. Lever in connection with the history of the Garswood coal contract, which figured so conspicuously in the Hunter trial; claiming that the matter was to be treated as confidential until some further communication was received from Mr. Lever. He concluded by saying that if Mr. Lever would help to send to prison a few of the bribers, who were worse than the bribes, instead of railing at the new Gas Committee, he would be doing good service. Mr. Lever replied to both these letters on the 23rd inst. With regard to that of Mr. Phillips, he indicated Sir James Farmer, the ex-Mayor of Salford, as a member of the Special Sub-Committee to whom he had a "strong and natural objection," inasmuch as Sir James preferred to see him criminally prosecuted rather than afford him the opportunity of stating at a personal interview what he had to say in reference to the frauds being perpetrated upon the ratepayers of Salford. As to the responsibility of the new Gas Committee, in reference to existing coal contracts, to which reference had been made by Mr. Snape, Mr. Lever said he pointed out that many of the contracts of 1886 were corruptly obtained, and would prove a heavy burden upon the people of Salford. He added: "The Council knew that these contracts could be replaced at a saving of £25,000 to the ratepayers, but they deliberately decided to seal these unfavourable contracts in September, 1887—seven months after my prosecution, and nearly twelve months after the old Gas Committee's purchase. But is it not a fact that within the last few weeks the new Gas Committee, for whom Mr. Snape pleads, have entered into a new contract for 25,000 tons of coal without any advertisement or competition?" As to the constitution of the Sub-Committee, he said: "The contention of Mr. Snape that the Corporation wish for an impartial tribunal will hardly hold water in the face of the fact that the Sub-Committee they appoint embraces no member who is not an ordinary or an *ex-officio* member of the Gas Committee. In objecting to my nomination of 'two members of the Council, with power to them to name a third,' the Council in effect say, 'We have in our body at least three men who are untrustworthy.'" With regard to the "neglect of duty" on the part of Mr. Snape, Mr. Lever denied ever having made such a charge. Mr. Snape last Friday replied to this letter. Referring to Mr. Lever's objection to the Sub-Committee, he said "What does Mr. Lever mean or want with regard to the tribunal? I have said that he desires to select his own judge and jury, and that this is a tribunal which is not satisfactory to the Salford Corporation, who offered him one which seemed to them fair. But Mr. Lever will not bring his case before them. Since then Mr. Phillips has suggested a tribunal to be selected by Mr. Oliver Heywood, the High Sheriff. I have suggested another. Will Mr. Lever accept none of these? Why does he ignore Mr. Phillips's suggestion and my own? Will he kindly say if he considers them fair, and if so, why he does not accept one of them? The Council are most anxious that if there are any frauds still going on, as Mr. Lever alleges, they should be stopped at once without a moment's loss of time; and it

certainly does seem surprising that if Mr. Lever has the proofs of these serious allegations in his possession, he is so reluctant to produce them. As I said before, it is nothing less than persecution to keep these charges hanging in the air, and the public mind in a ferment of suspicion, without at once bringing the proofs to the front." On the subject of the coal contracts, Mr. Snape said: "Respecting the contracts Mr. Lever says:—'I know that I pointed out that many of the contracts of 1886 were corruptly obtained.' This is news to me. I know nothing of it. The contracts were accepted by the Corporation on Oct. 6, 1886, three days before my interview with Mr. Lever, when for the first time I heard anything approaching even a credible story with regard to frauds in the gas management; and then, as I have said, no names were given, and certainly nothing was said to me with regard to corruption as to the new contracts, except that both Mr. Lever and I inferred that there was a probability of corruption in regard to them if the story he then told me was true. But he certainly gave me no proof of corruption in regard to them, nor, so far as I am aware, has he given any since to anybody else. I opposed the sealing of the contracts in December, 1886, because, although I had strong suspicion from what Mr. Lever told me, I had no proof; and I was away for my holidays in September, 1887, when the contracts were sealed, or I should have opposed it again. But I never heard that Mr. Lever had produced any proofs. The position of the Council and the Gas Committee was a difficult one. The contracts had been accepted by resolution of the Council, as before stated, and deliveries had begun on Nov. 1, 1886. It is true the actual contracts were not sealed, and one of the first questions that arose at the Investigation Committee was whether, under the circumstances, the whole of these contracts ought not to be cancelled. But on consulting our legal advisers we were told that the contracts having been accepted, and part deliveries having been made thereunder, although the seal had not been attached, they were legally binding unless we could prove fraud with regard to each specific contract. This we were not able to do, nor are we able to do it yet; and therefore the contracts still stand. If Mr. Lever succeeds in enabling us to prove fraud in regard to any one of them, I promise him it will not be very long before that particular contract is cancelled, and an action commenced for the recovery of any money out of which the Corporation has been defrauded. Mr. Lever asks: 'Is it not a fact that within the last few weeks the new Gas Committee, for whom Mr. Snape pleads, have entered into a new contract for 25,000 tons of coal without any advertisement or competition?' Mr. Lever has not the hardihood to say that a new contract has been entered into, but his language certainly suggests it; the fact being that one of the present contracts is for 39,000 tons of coal to be delivered by the end of 1889. The present Gas Committee find they will not want this quantity of coal for a long time, and that if they take it in, they would have to stack it in their yard, where it would deteriorate, and they would lose interest upon it. So they have induced the contractor to cancel a portion of the coal still undelivered, and to deliver in substitution therefor an equal money value of another kind of coal which the Committee actually do want. This variation of the contract, when properly explained, will, I am sure, meet with the approbation of everybody; whereas Mr. Lever tries to bring it up as a charge against the Gas Committee that they are improperly entering into new contracts for coal without advertising for the same." Mr. Snape concluded by again appealing to the public to give the new Gas Committee fair play, and to Mr. Lever to come forward in a manly, straightforward way, and state his case fully if he has any charges to make against anybody. He added that Mr. Lever might depend upon it that, in the spirit at present animating the Salford Council, they would cleanse their various departments from all proved corruptions and irregularities.

As bearing largely on the matters alluded to in the correspondence above summarized, it will be of interest to reproduce a letter, on "Coal Commissions," addressed by the President of The Gas Institute (Mr. H. Woodall, M. Inst. C.E.) to the *Manchester* papers last week. It was as follows:—"This subject is evidently occupying so much of public attention in the neighbourhood of Manchester, that I venture to hope you will afford me space for a few words upon an aspect of the question which hitherto has received too little consideration. It is generally accepted that the commission system is a most reprehensible one, and that the sooner it is abolished the better. But it is not so generally known that, unsuspected by most people, and even by officials themselves, it is being exercised to the prejudice of public interests in ways that would be ludicrous were they not so exasperating. On one occasion I found that an intimate friend had been paying a commission to a casual acquaintance on coals supplied to me, and that, naturally enough, he had given me credit for having shared the plunder. In another case a man whom I know neither by name nor sight went to a colliery with a statement that he had influence with me, and for a consideration could secure an order. A sample was tested and a contract made; and it was not until another year that I learned we had been paying 6d. a ton on 10,000 tons to this very clever fellow, whose acquaintance I had still to make. Now, what I want to ask is, Why should colliery proprietors put their trust in middlemen? And why should companies or corporations buy through them? The credit of a gas concern is practically as good as that of Government itself. There is therefore no need of a negotiator; and manifestly a company is surer of being supplied with what it bargains for when dealing with the colliery direct. Manchester has probably lost more than any other town in Britain by persistent disregard of these self-evident truths; and it will be a happy day for ratepayers, councillors, and officials when the blunder is recognized and corrected."

THE CHARGES IN CONNECTION WITH THE HALIFAX GAS-WORKS.

At the Meeting of the Halifax Town Council last Tuesday—the Mayor (Mr. Alderman J. Booth) in the chair—the question of giving an indemnity to Mr. Alderman Riley with regard to the charges made against him by Mr. T. K. Fox, of being guilty of certain malpractices in connection with the Corporation gas undertaking, was under discussion. It will be remembered that Mr. Riley's Solicitor (Mr. W. H. Boocock) sent to the Town Clerk (Mr. Keighley Walton) a draft form of indemnity which he wished the Mayor to sign prior to any action against Mr. Fox being taken. The Town Clerk objected to certain clauses of the indemnity, and returned it amended to Mr. Boocock. The indemnity is as follows; the words in italics being those struck out by the Town Clerk as objectionable, and the words in brackets those inserted by the Town Clerk, acting on behalf of the Mayor:—

"This Indenture, between James Booth, of Halifax, in the county of York, manufacturer, the Mayor of the said borough of Halifax, of the one part, and James Turner Riley, of the other part.

"Whereas one Thomas King Fox hath, after a certain indemnity had been given to him by the said James Booth, made charges or allegations against the said James T. Riley, imputing to him malpractices in connection with the Halifax Gas-Works, which said charges or allegations were contained in a writing signed by the said Thomas King Fox, and forwarded by his directions to the said James Booth; and whereas it hath been thought desirable that the truth of the said charges

and allegations of malpractices should be investigated in a Court of Law, and that the said James T. Riley should commence forthwith an action for damages for defamation of his character against the said Thomas King Fox; and whereas the said James Booth requested the said James Turner Riley forthwith to commence such action; and whereas the said James Turner Riley hath agreed so to do upon being indemnified as hereinafter set forth:

"Now this indenture witnesseth that, in consideration of the said agreement, the said James Booth doth hereby covenant and agree with the said James Turner Riley, his executors and administrators, that in the event of a verdict being found or judgment given in such action in favour of the said James Turner Riley [for the sum of £10 or upwards, and costs], as also in any event, unless the said James Turner Riley shall in the said action be found or proved guilty of malpractices in connection with the Halifax Gas-Works, in the shape of corruptly receiving money, by way of commission or bribe, on coal or other things purchased by the Corporation, he, the said James Booth, will save harmless and keep fully indemnified the said James Turner Riley, his executors and administrators, from all costs (as well between solicitor and client as between party and party), and as well his and his executors' or administrators' own costs as costs he or they may be liable to pay the opposite side or other parties, and all charges, disbursements, and expenses of what nature or kind soever, which he, the said James T. Riley, his executors or administrators, or his or their duly authorized solicitors or agents, shall properly incur (as well before as after action brought) in, about, or relating to the obtaining information for, or conducting of, such action or of the said action, or in or about the bringing of the same to trial, or the trying of the same; it being the full intention and meaning of these presents that the said James Turner Riley, his executors or administrators, should not be put to or incur any expense personally in the event herein provided for, and that in the events herein provided for, or in any of them, whatever expense the said James Turner Riley, his executors or administrators, may incur or be put to, he and they shall be fully recouped, reimbursed, and indemnified by the said James Booth.

"And the said James Booth, on behalf of the Corporation of Halifax and their officials, doth hereby further covenant and agree with the said James T. Riley, his executors and administrators, that the said Thomas King Fox shall not in such action set up any plea or defence on the ground of privilege, and that every reasonable opportunity and facility shall be given to him, the said James Turner Riley, and his solicitors, for inspecting and taking copies of all the Corporation books relating to the gas-works, and also all tenders, contracts, and papers relating to or affecting the working and management of the said gas-works.

"And the said James Turner Riley doth hereby covenant and agree with the said James Booth that he will, within one week of the execution of these presents by the said James Booth, commence an action for damages for defamation of character against the said Thomas King Fox, and that in such action an opportunity shall be afforded to the said Thomas King Fox, of alleging and substantiating, if he can, that the said James Turner Riley was or had been guilty of malpractices in connection with the Halifax Gas-Works, in the shape of corruptly receiving money, by way of commission or bribe, on coal or other goods purchased by the Halifax Corporation for the said gas-works.

"In witness," &c.

On the minute in the agenda relating to this matter being reached, The Mayor called upon the Town Clerk to read some correspondence he had received on the subject.

The TOWN CLERK read the following letter from Mr. Riley's Solicitor:—"Dear Sir,—I have now seen my client upon your alterations in the draft deed of indemnity, and these alterations raise two important points: (1) The indemnity is limited by making it dependent upon Mr. Riley obtaining a verdict of £10 or upwards and costs against Mr. Fox. You will, of course, see that in certain events Mr. Riley may, with this limitation, have to pay his own costs, whilst Mr. Fox, according to the terms of his indemnity, will not; and this although Mr. Fox may not succeed in proving anything against my client. It is only reasonable to ask that Mr. Riley should be indemnified from all costs in any event save verdict for the defendant. (2) The draft, as altered, gives Mr. Fox unlimited scope to make any charge or allegation against my client in anything he may have done or omitted to do in connection with the gas-works. To this I cannot advise my client to agree. Referring to the indemnity given to Mr. Fox (which I take from the print in the newspapers, as I have no other copy), it is recited that Mr. Fox has 'written certain letters to Keighley Walton, Esq., the Town Clerk to the said borough of Halifax, concerning the supply of coals to the said gas-works; and further, 'that the said Corporation expressed a desire to have the said statements in the letters of the said T. K. Fox fully and thoroughly investigated;' and the first clause of such indemnity provides that, on the signing thereof, Mr. Fox shall state 'in writing the name or names of the person or persons referred to in his letters as the object of the charges therein referred to.' But in the statements made by Mr. Fox in pursuance of his indemnity, these letters are never referred to, and my client is only mentioned in two of the statements. The first of these statements we may pass by for present purposes, as it merely states Mr. Fox's opinion that Mr. Riley is unfit to be Chairman of the Gas Committee; the latter charges my client with malpractices, which may mean a great deal or nothing. Now, taking Mr. Fox's letters, the words of the indemnity, and statements made by the Mayor and others, the public have interpreted them as accusing Mr. Riley of having been guilty of the offence of receiving bribes or commission on coal bought for the gas-works. If Mr. Fox, by charging my client with malpractices, means such practices as these, my client is prepared to proceed against Mr. Fox, and defies him to prove them. The draft indemnity, as submitted to you by me, goes further than this, because it includes not only coal, but any other goods purchased by the Corporation for the gas-works. I must therefore ask that the provision that the indemnity shall be in force unless my client 'be found or proved guilty of malpractices in connection with the Halifax Gas-Works in the shape of corruptly receiving money by way of commission or bribe, on coal or other goods purchased by the Corporation' (and which you have struck out), be allowed to remain. These are the grounds upon which my client is prepared to meet Mr. Fox; and if Mr. Fox's charges mean less than these, he cares not to disprove them further than he has already done by stating that they are not true, and, unless the draft be agreed to as submitted, I cannot advise my client to accept the indemnity." He explained that there were, so far as he could gather, four objections to the alterations. As to the first objection, what the Corporation wanted was precisely on the same lines as the indemnity given to Mr. Fox. Secondly, Alderman Riley declined to face unknown charges; but the fact was that the Corporation did not know what the charges were, but, if action was taken, could call upon Mr. Fox to state the particulars of his charges, and could pin him down to state them. The last objection was the most important one, however. Alderman Riley declined to commence any action unless Mr. Fox would charge him with taking commission or bribes on coal or other goods purchased by the Corporation. It was not yet known whether

Mr. Fox would make such a charge, or could do so; if not, then whatever other charges be made and proved, and however serious they were, Alderman Riley was still to be indemnified. In fact, Mr. Fox might prove twenty charges of malpractices; but unless one of these twenty was a malpractice by taking commission or bribes, Alderman Riley was to be held innocent, and to be indemnified.

The MAYOR: I have to move the following resolution:—"Mr. E. G. Wrigley and Mr. William Carr having declined to commence any action for libel against Mr. T. K. Fox, and Alderman Riley having declined to take proceedings against Mr. Fox except with an indemnity by the Council, in terms which the Council cannot agree to, resolved that the Sub-Committee (the Mayor, Mr. Alderman Ramsden, and the Town Clerk) be authorized and requested to prosecute their inquiries, and institute such proceedings, civil or criminal, as they may be advised."

Alderman POLLARD said he had great pleasure in seconding the motion. The statement made by the Town Clerk had much surprised him. He had been under the impression that the Council agreed at its last meeting to give the same indemnity to Alderman Riley as was given to Mr. Fox, and nothing more. If this was not satisfactory, let the Council take what proceedings they might be advised, whether civil or criminal.

Alderman HOLDSWORTH said he should like to ask the Town Clerk if "bribes" were not mentioned in the indemnity. That was a much broader term than "commission," and meant money received in any way for goods sold to the Corporation.

The TOWN CLERK replied in the affirmative, but pointed out that Alderman Holdsworth did not appear to him to catch the point aimed at by the clauses objected to in the indemnity. It mentioned bribes; but it stipulated, "as also in any event," unless Alderman Riley was found guilty of receiving money by way of commission or bribe, &c. Now they did not know what Mr. Fox intended to prove, or what form of malpractices he alleged; and, therefore, if he proved twenty other charges of malpractices against Alderman Riley, unless he proved a malpractice by way of commission or bribe on coal or other goods purchased by the Corporation, he would fail if the clause in the indemnity stood as submitted.

Alderman MIDGLEY: Am I right in concluding that Alderman Riley is prepared to accept an indemnity, provided it covers any charge of corruption as alleged against him?

The TOWN CLERK: No.

Alderman RILEY said he should like to make a statement.

The Mayor said he could not allow him to speak.

Alderman LONGBOTTOM referred to certain statements which seemed to have gone forth to the public to the effect that the Lord Chancellor was to be asked to appoint a Royal Commission to inquire into the subject of the gas scandal, and also another rumour that the Local Government Board were to be asked to open an inquiry. He did not know, with regard to the first statement, that a Royal Commission could be appointed by any authority but Parliament; and with regard to the second, he did not apprehend that the Local Government Board had authority or control over gas-works owned and managed by a municipal corporation.

The TOWN CLERK said he quite agreed with Alderman Longbottom that neither the Lord Chancellor nor the Local Government Board had anything to do with the matter.

Alderman RILEY: I wish to ask the Town Clerk if I, having received a notice to attend this Council meeting, have not a right to speak.

The TOWN CLERK: No member of the Council can speak on subjects in which he is personally interested.

The resolution was then put, and carried without a dissentient.

MR. ALDERMAN RILEY ON HIS DEFENCE.

Last Friday evening the annual ward meeting of the burgesses of the Market Ward, Halifax, of which Mr. Alderman Riley is the presiding Alderman, was held; and, in view of the recent proceedings in the Council, was well attended. Mr. Riley occupied the chair, and after a few introductory remarks, in the course of which he assured the burgesses that there had been no desire on his part to shirk the meeting, he asked permission to detain them for a short time in reference to the subject which was so prominently before the town—viz., the "gas scandal." He then said: It is now nearly 17 years since you first did me the honour of electing me as one of your representatives, and I have ever since been a member of the Halifax Corporation; and for the last 12 years I have been Chairman of the Gas Committee. During the whole of this period I have always acted as I thought best for the interest of the ratepayers of this town; and I defy the Mayor, or Mr. Fox, or any other person, to point out, in my corporate career, one single instance of dishonourable conduct, or any violation of my duty towards you, my electors, or the ratepayers generally. Mr. Fox has made two so-called charges against me—namely, that I am unfit to occupy the position of Chairman of the Gas Committee; and that I have been guilty of malpractices in connection with the gas-works. Now, what do these allegations amount to? Whether I am or am not fit to be the Chairman of the Gas Committee is merely a matter of opinion; and I ask you to decide this point for yourselves. I think, however, that this charge is sufficiently answered by the fact that the price of gas in this town has dropped from 4s. to 1s. 9d. per 1000 cubic feet during the time I have been Chairman of the Gas Committee; that in 1875, with a capital of £233,523 17s. 5d. invested in the works, the make was 264,038,000 cubic feet, whilst in 1887, with a capital of £290,744 15s. 4d., or about £53,000 more than in 1875, the make was 527,703,000 cubic feet, or practically double that of 1875; that during this period the gas-works have been transferred from a state of chaos to one of first-class order; and that there is scarcely another place in England which has gas at so low a rate as we have here. The latter charge also is equally vague. No particulars are given as to the nature of the malpractices of which Mr. Fox accuses me. The term "malpractice" is of very wide and indefinite import. It sometimes means a great deal, and it sometimes means very little or nothing at all. Literally speaking, negligence, carelessness, or inattention are malpractices. No man, even in his own business, is perfect; and it would have been an impossibility for me to have occupied the position of Chairman of the Gas Committee of this Corporation for upwards of twelve years without having been guilty of one or more of the above malpractices. If this is the sense in which Mr. Fox uses the term "malpractice," then this charge, too, would be of so trivial a nature as probably to be held not to be libellous. In common parlance, however, the term "malpractice" signifies criminal conduct; and, taken in this sense, and in conjunction with what the Mayor has said—viz., that the Corporation has been defrauded out of several thousands of pounds—the public have been given to understand that I have been guilty of receiving commissions and bribes. Gentlemen, I assert most positively that there is not the slightest particle of truth in this base insinuation; and I offered to sue Mr. Fox on this ground. The Mayor and the Town Clerk, however, have advised the Corporation not to accept this offer. This, gentlemen, is tantamount to saying that no such charge can be proved against me. I leave the ruling of the Mayor and Town Clerk, in refusing to hear me speak at the Council meeting on Tuesday last, to speak for itself; and, I am sure, gentlemen,

that you will all agree with me in saying that it was unjust, and that thereby I was placed at a great disadvantage. During the whole of the time that the subject has been before the public, I have never been consulted by the Mayor in reference thereto. Surely he ought to know that one side of a question always seems very plausible until the other side has been heard; and had he spoken to me, I have no doubt that I could have shown him, as far as I am concerned, that there is not the slightest foundation for Mr. Fox's charges. I do not, however, intend to indulge further in crying out against the injustice done to me; and seeing that the Council has passed a resolution to prosecute their inquiries by means of civil or criminal proceedings, I can only add that I am very glad, and that, knowing that I am perfectly innocent, I am prepared to meet whatever legal proceedings, if any, they may adopt. I have been told to-day, on pretty good authority, that the matter is boiled down to this—that the Corporation intend to sue Mr. Wrigley, contractor for cannel coal, for deficiency in the quality of coal. Mr. Wrigley was in the town yesterday, and had an interview with the Mayor and Town Clerk, and that is the result of their deliberations. We shall have to wait our time. I have no fear that anything will be discovered that can incriminate me in the slightest degree. I have an inward consciousness that I have done nothing wrong, and no amount of sifting can prove that I have occupied my position in the Corporation to benefit my pocket in any form; and I defy the Mayor, or any court of inquiry in the world, to prove that. Of course, I know what I have done—I ought to know; and there is nothing that has kept me up through this great trial but the inward consciousness that I have done nothing to betray the confidence that you reposed in me 17 years ago.

There have been further references to the matter at other ward meetings. Mr. Brear, a member of the Gas Committee, was questioned about it at the meeting he addressed last night week, and stated that there was a man employed to weigh the coal, and if the Committee had been deceived, it was nothing they could help. The weighman had told him it was impossible for him to weigh all the coal, owing to the lack of siding accommodation; and he would need a couple of horses or an engine to move the trucks on to the machine. He (Mr. Brear) once asked Mr. Carr if he found the coals came up to contract. He said he did; and when he did not, he would at once speak to the Committee about it. In answer to further questions, Mr. Brear said the weighing-machine was only out of repair four days after the Committee knew about it. All the coals would be weighed by the Railway Company on their own behalf. Alderman Midgley, at a meeting over which he presided on Wednesday night, said the question as to the weighing of the coal should be inquired into further, so as to ascertain whether anybody had given the weighman orders not to weigh the coal. If he had received such orders, then somebody was seriously to blame; and whoever it was—man or master—an example should be made of him. If, as had been expected, there were hindrances in the way of the trucks being weighed, these hindrances should be removed, even if it cost £500 or £600 to do it. He had heard the remark that they should sweep away the whole of the Gas Committee. He did not approve of such a course, for they might depend upon it that the members of the Committee were as honest and straightforward as they themselves were. The Committee had made a mistake; and no doubt every member felt this as acutely as anyone outside.

The *Halifax Courier* states that "on Thursday afternoon the Mayor, Mr. Alderman Ramsden, and the Town Clerk had an interview, at the Town Hall, with Mr. Emor G. Wrigley and his Solicitor (Mr. Cobbett, of Manchester), having reference, no doubt, to the matter alleged against Mr. Wrigley—viz., sending coal of inferior quality to that contracted for. What the result of the inquiry was, of course, kept private. It is not unlikely, however, that proceedings may be commenced against Mr. Wrigley to recover the difference, if any, in the value of the coal supplied and that agreed for. It may interest our readers to know that from 1881 to 1886 hand-picked coal was not contracted for by Mr. Wrigley; but in the latter year, we are informed, the contract was altered, and 5000 tons of hand-picked coal were to be sent. In the following year a similar contract with him was again entered into; and this year—last May, we believe—6000 tons were ordered of him of the same quality. If proceedings be taken, and the coal now supplied be found to be other than that agreed for, it is not unlikely that the contract will be cancelled; and the action would then be to recover the difference in the value of 10,000 tons supplied in 1886 and 1887, and on the quantity delivered so far since the last contract."

THE GAS-WORKS OF THE HUDDERSFIELD CORPORATION.—The new gas-works of the Huddersfield Corporation in the Leeds Road were started on the 27th ult. After an inspection of the new retorts and the other machinery and apparatus, which has been erected under the supervision of the Corporation Gas Engineer (Mr. J. Burgess), the Committee proceeded to the station meter, and afterwards to the new gasholder, where the ceremony of turning the valve was performed by Miss Stocks, the daughter of the Vice-Chairman of the Gas Committee.

THE HENDON LOCAL BOARD AND ELECTRIC LIGHTING.—At the meeting of the Hendon Local Board on Monday last week, Mr. Yule brought forward a motion in reference to the electric lighting of the district, and said his object in doing so was to obtain a more economical system. At present they paid 4s. 6d. per 1000 cubic feet for gas, which, as compared with London, was very high. The following motion was, after a very brief discussion, unanimously agreed to:—"That the Solicitor be instructed to inquire as to the cost of adopting a system of electric lighting as at Barnet; the Surveyor to report as to the estimated relative cost of lighting the more populous parts of the district as against gas."

BOMBAY GAS COMPANY, LIMITED.—The report of the Directors of this Company and the accounts for the half year ending June 30 last, which will be submitted at the meeting of the shareholders on the 7th prox., are satisfactory so far as the receipts are concerned. Compared with the corresponding half of last year, the revenue from the sale of gas and meter-rental displays an increase of £1102 13s. There has also been an improvement in the sale of coke, tar, and fittings. The unsatisfactory feature in the half-year's operations is the serious loss in exchange, which was £14,947 10s., on the £32,000 remitted in the six months; the average rate being 1s. 4½d. per rupee. Of this loss £8474 10s. has been charged to profit and loss, and the balance (£6500) written off exchange equalization account; leaving £1979 5s. 5d. at the credit of the latter account. The amount at the credit of profit and loss is £8859 10s., which, with the balance brought forward (£156 10s.), makes a total of £9016. Out of this sum the Directors have placed £500 to the reserve fund for depreciation of plant, &c., and declared an interim dividend of 3½ per cent., amounting to £8400; leaving £116 to be carried forward. The Directors regret to announce the retirement, through ill-health, of Mr. G. A. Northover from the position of Auditor. Under the Articles of Association, they have appointed Mr. E. A. Pinders to fill the vacancy until the next ordinary meeting of the shareholders.

THE BRITISH GASLIGHT COMPANY AND THEIR ACCOUNTS.

At the Meeting of the Hanley Town Council last Tuesday, the report presented by the General Purposes Committee showed that the following resolution had been adopted by the Gas Sub-Committee:—"That this Sub-Committee, having examined the statement of accounts of the British Gaslight Company, Limited, for the year ended June 30, 1888, hereby expresses its satisfaction that, notwithstanding the correspondence which has taken place between the Company and the Corporation, and the reduction in the price of gas, the Company have omitted the items of depreciation and insurance from such statement, which shows that in addition to paying all dividends and arrears of dividends, together with £973 4s. 8d. balance of costs of the inquiry before the Recorder, they have for the first time a reserve of £717 9s. 11d." In moving the adoption of the report, Alderman Powell said the Company had carried out the promise they made to the Corporation some time ago not to charge in their statement of accounts for depreciation and insurance. All through their dispute with the Company, the Corporation had contended that the Company had no right to do this; and now they had ceased to do it. The result was that, after reducing the price of gas from 3s. 6d. to 3s. per 1000 cubic feet, they had been able to do extraordinary things. For instance, they had paid off a large sum for what in 1884 was a deficiency of dividends; they had paid the full amount of their statutory dividend upon £12,610; they had further paid dividends at the rate of 7½ per cent. upon £30,000, and at the rate of 5 per cent. upon £34,702. They had even done more than this; for somehow or other they had found out that, whereas in 1884 there was owing to the London Board a sum of £3397, the London Board now owed to the Potteries undertaking a sum of £736. The Company had now, for the first time, created a reserve fund of £717 9s. 11d., and had shown, also for the first time, by a fair statement of accounts what an immensely profitable undertaking the gas-works were. They were so profitable, indeed, that he hoped the burgesses of Hanley would not be contented until the undertaking belonged to the Corporation. The report was adopted.

CEARA GAS COMPANY, LIMITED.

The Annual General Meeting of this Company was held last Friday, at the London Offices, 9, Queen Street Place—Mr. HORATIO BROTHERS, C.E., in the chair.

The SECRETARY (Mr. T. Guyatt) read the notice convening the meeting; and it was agreed to take as read the Directors' report and accounts for the year ending June 30 last, an epitome of which was given in the JOURNAL last week (p. 734).

The CHAIRMAN, in rising to move—"That the report and accounts be received and adopted," said he had pleasure in remarking that the balance-sheet which they had before them was perhaps the best that had ever been submitted to the shareholders. It was true that the Board did not recommend quite so large a dividend as they had previously declared; but this was a matter of policy. The Directors considered it best to strengthen their position by increasing the reserve fund. The accounts on the present occasion called for very little remark. There was an increase of £356 in the receipts from private consumption, and of £280 in those from the public lamps—making a total increase of £660 in the revenue from gas. There had also been an improvement in residual products to the extent of £428. In other words, the residuals produced £920, against £496. The total increase in the revenue from all sources was £1278. On the expenditure side of the account there was a decrease of £221; but in the balance-sheet of last year there appeared an item of "tax on meters, £590." This tax the Board expected would be abolished. It was part of the arrangement that the Company made with the Provincial Authority, when they entered into an agreement to provide 300 more lamps, that this tax should be no longer levied. It was now awaiting the decision of the Legislative Assembly; and they hoped it would be confirmed. Deducting this £590, the expenditure was practically £369 more than in 1887. Of this increase, £318 fell to coals. He might, however, remark that their Manager (Mr. T. M'Making) was scarcely to be blamed for this, because in regard to the coal there were certain circumstances over which he had no control. They had no doubt that in the future the make of gas would be considerably increased. Although they had not produced so much gas per ton of coal carbonized, they had sold the same quantity of gas per ton. The other items of the account did not show any very remarkable or noteworthy changes. The profit exhibited a gratifying increase—from £2977 in 1887 to £4476 now. To make a fair comparison, however, the tax on meters levied in 1887 amounted to £590, and not being charged in 1888, must be deducted, which would reduce to £986 the increase of profit over 1887. The capital account, the shareholders would see, had been augmented by a sum of £2741 6s. 5d. This was occasioned by the additional lamps and fixing them, and new apparatus and coal stores. In the current year there would also be an increase, as the Board were extending the works to meet the requirements of their customers. He anticipated that this increased demand for gas would continue, as it was now doing; and there was no doubt that in the future they would have to make further provision for it. As to the prospects of the Company, he might say that he looked forward with a great deal of pleasure. It would be observed that, instead of dividing the whole of the amount earned, the Board recommended that £1000 should be put to the reserve fund. By this means they increased the stability of the Company and the certainty of the dividend.

Mr. J. DARELL BLOUNT seconded the resolution, which was at once agreed to.

On the motion of the CHAIRMAN, seconded by Mr. BLOUNT, it was decided to add £1000 to the reserve fund, and to pay dividends at the rate of 10 per cent. per annum on the preference shares (less income-tax), and at the rate of 11 per cent. per annum on the ordinary shares, free of income-tax. This will make, with the interim dividend, 8 per cent. for the year.

Mr. A. J. KINO proposed, and Mr. F. W. BROTHERS seconded, the re-election of the Directors retiring by rotation (Messrs. Horatio Brothers and F. A. Wallroth).

The motion was carried unanimously, and Mr. BROTHERS returned thanks.

On the motion of Mr. WHITE, seconded by Mr. ANDREWS, Mr. Robert King was elected Auditor of the Company, in the place of Mr. R. W. Wilbraham, who retired, and did not seek re-election.

The CHAIRMAN next proposed a vote of thanks to the Manager, the Secretary, and the Officers of the Company. In doing so, he read an extract from the *Libertador*, of Aug. 27 last, giving a report on the popular fêtes promoted by the Town Council of Fortaleza. In the course of the report it said: "A ball in the open air in our picturesque garden was the great attraction of the fêtes. The garden was a gem of elegant and festive ornamentation, presenting an illumination which gained unanimous praise for the zealous and indefatigable Manager of the Ceara Gas Company (Mr. M'Making), to whom the President of the Province expressed the satisfaction which he felt for the way in which that gentleman had discharged his arduous task in a few hours."

The motion was cordially agreed to.

The SECRETARY responded in suitable terms, remarking that Mr. M'Making being abroad, he would very much appreciate the vote, as necessarily he had not too much of the comforts which they had this side. A vote of thanks was always much more pleasing to a Manager abroad than it would be supposing he were in England.

Mr. ANDREWS proposed an acknowledgment of the services of the Directors; eulogizing the manner in which they had conducted the concern. He considered it very politic on the part of the Directors to recommend the substantial addition they had made to the reserve fund.

Mr. R. KING seconded the proposition, which was agreed to *nem. con.*

The CHAIRMAN having briefly acknowledged the vote, the proceedings terminated.

THE DUBLIN CORPORATION AND ELECTRIC LIGHTING.

A Special Meeting of the Dublin Town Council was held on Monday last week—the LORD MAYOR (the Rt. Hon. Thomas Sexton, M.P.) in the chair—to consider a motion to the effect that the Corporation should apply to the Board of Trade for power to supply electricity within the area of the city of Dublin.

Mr. ROBINSON, in moving a resolution embodying the above proposition, said the question had been before the Council for a long time, and so far there had been no practical outcome, owing to the opposition they had received from the Dublin Gas Company. When the Committee of the Whole House had this question under their consideration, they determined to apply to the Board of Trade for a Licence to use electricity for public purposes only—that was to say, that the Corporation should, if they pleased, light the streets of the city with the electric light. They had power, if they desired, to apply for liberty to use electricity for private purposes also; but the Committee decided only to ask for it for public purposes, thinking the Gas Company would not interfere with the Corporation in regard to the manner in which they wished to light the city. But the Company had offered them the most determined opposition. He thought the time had now come when the Corporation should apply also for a Licence for private lighting, in order to break down the monopoly which the Gas Company had succeeded in obtaining over the city—a monopoly which they evidently considered should extend not only to gas but to electricity; for they had served notice that they intended to apply for a Provisional Order to enable them to furnish electric lighting both for private and public purposes. This was a thing against which the Corporation ought to make a determined stand.

Mr. HEALY seconded the motion. He said he was exceedingly pleased at the project to light the city by electricity, and so were a large number of ratepayers with whom he had conversed.

Mr. P. DORAN said he should like to know the probable expense of the scheme. He should much prefer that the Corporation would borrow £9000 to build dwellings for the working classes, and manage with their present light, rather than take up electricity, which had been a failure in other towns.

The HIGH SHERIFF (Mr. Alderman J. Winstanley) said he expected that the mover of the resolution would have shown where the profit would come to the citizens of Dublin, and would have quoted the cases of towns in England, Scotland, or elsewhere, where the light was used, and show what benefit the citizens had derived from it. But the only thing they had heard mentioned was that the Gas Company had gone to the Board of Trade to protect their rights against the inroads of the Corporation; but if the Directors did not do this, they would have been wanting in their duty to their shareholders. He had no objection to certain members of the Corporation sporting with the ratepayers' money; but before a request was made for the subscription of capital to this undertaking, it should be shown that there would not be a considerable loss to the citizens.

Mr. DENNEHY thought the members ought to be careful that, in the proceedings they were taking, they did not bring themselves under a very serious liability as regarded the waste of public money. They were going to deal with a site from which the Corporation derived £200 a year; and he was certain the water power there, though ample for public lighting, would not be sufficient for private lighting. They ought not to forget what happened to the Dublin Electric Lighting Company. He should be surprised if any Committee of the Council or any citizens of Dublin at the present day would be able to realize a profit when the Board of that Company failed ignominiously.

Mr. MAYNE said the gentlemen who opposed the motion appeared to be all influenced by one fear—the loss to the citizens of Dublin. They should remember that the Dublin Electric Light Company was wound up, not because they were not making profits—they were making them—but because they had not sufficient capital, and could not get any more at the time, owing to a panic which had set in in electric lighting shares in England.

Mr. DOHERTY thought they ought to establish a right to light the city, and have control over the lighting of the city, whether by gas, electricity, or anything else.

Mr. ROBINSON having replied,

The LORD MAYOR put the motion. In doing so he said the Directors of the Gas Company were clever business men; and they evidently thought electric lighting was a profitable undertaking, for they wanted a Licence for it. They would not move unless they saw a considerable profit—10 or 20 per cent. If the speculation was good enough for them, it was good enough for the Corporation, who did not wish to pay any dividend.

The motion was carried without a division; and it was subsequently resolved to appoint a Committee of 15 members to take the necessary steps for obtaining the Provisional Order.

AN ELECTRIC LIGHTING SCHEME FOR IPSWICH.—At the meeting of the Ipswich Town Council last Wednesday, sanction was given to Messrs. Paris and Scott, Limited, of Norwich, to lay down cables for electric lighting and power purposes in certain portions of the borough.

ELECTRIC LIGHTING AT BARNET.—At the meeting of the Barnet Local Board on the 9th inst., a Committee presented a report to the effect that as the electric lighting contractor had failed in his contract, and the light was indifferent, he be given 14 days' notice to terminate the contract. At the urgent request of certain members of the Board, it was decided to suspend the notice for a fortnight, to see if the contractor made satisfactory progress. The matter accordingly came before the Board at their meeting last Tuesday, on the question of serving the notice; and Mr. Pooley observed that, the report and recommendation of the Committee having been agreed to at the previous meeting, their duty was clear. They must have some report as to the progress made, and if it was unsatisfactory, all they had to do was to proceed with the resolution. The Surveyor (Mr. W. H. Mansbridge) submitted a report as to the general condition of the lighting from the 3rd to the 22nd inst.; and, in answer to the Chairman (Mr. C. Stephens), said he could not regard it as satisfactory. It was therefore proposed that the notice suggested by the Committee should be served on the contractor. An amendment was, however, brought forward to grant him another week's grace; and if by that time satisfactory progress had not been made, to give him notice to terminate his contract. Eventually this was agreed to.

EDINBURGH AND LEITH GAS COMMISSION.

At a Meeting of the Edinburgh and Leith Gas Commissioners on Monday last week—Lord Provost Clark presiding—the Works Committee recommended that the burgh of Leith should be placed on the same footing as Edinburgh in regard to the lighting of the public lamps. Attention was directed to the lighting of the suburbs. Mr. Kinloch Anderson doubted whether the burners used were of sufficient size. There was, he said, a great deal of grumbling about the matter. He had had a conversation on the subject with the Engineer, who informed him that formerly the city allowed the Gas Company 2 cubic feet of gas per lamp per hour; but this amount had frequently extended to 4 feet. Now, however, the Engineer was restricted to 1½ feet per hour. In reply to the Provost, it was stated that this change was made last year by the Gas Company. A brief discussion ensued on the subject, and subsequently the matter was remitted to the Works Committee. In regard to the application of the retort-house men at the Leith Gas-Works to have their wages restored to the same figure as before May, 1886, the Finance Committee reported that they were of opinion that the wages and hours of work should be left entirely with the Engineers. Bailie Archibald moved that Mr. Linton pay the men the same as before May, 1886. The Lord Provost said that if they took this power from the Managers, it would put them in an inferior position. Surely it was right that the men should deal with the Manager, and not with the Commissioners; otherwise they would individually have constant complaints from workmen. On a division, the report of the Committee was adopted by a majority. It was stated that the Inland Revenue Commissioners had fixed the stamp duty upon the Gas Commissioners' Act of Parliament at £3973; and instructions were given to pay it. Messrs. Davidson and Syme wrote enclosing a summons of declarator and interdict and damages at the instance of Messrs. G. Mackay and Co., Brewers, of Canongate, against the Edinburgh Gaslight Company for fouling a well. The Lord Provost remarked that he thought this was a claim against the old Company; but eventually the subject was sent to the Law Committee with powers.

THE GAS AND WATER UNDERTAKINGS OF THE NOTTINGHAM CORPORATION.

At a Meeting recently held at Nottingham under the auspices of a local Liberal Association, Mr. Alderman Goldschmidt delivered an address on the finances of the Corporation. He quoted statistics showing that the rateable value of the borough has increased from £297,660 in 1871-2, to £914,520 at the present time; the rates being respectively 4s. 6d. and 5s. in the pound. The last-named figure is a reduction of 2d. on the amount levied in 1886-7. Speaking on the subject of the productive debt of the Corporation, he said it comprised the money raised on the security of the gas and water undertakings. "For these," he said, "we had to pay a heavy price, but made a good bargain nevertheless. We owe for gas £873,113, less sinking fund, £12,770; leaving £860,343. Not one penny of this, however, will fall on the rates. The gas undertaking pays its own interest, provides a sinking fund, and has already a reserve fund of £100,000. This sum, if invested at 3½ per cent. compound interest, would produce £800,000 in 60 years, and thus pay off the whole of the gas debt; but as we are, in addition, providing a sinking fund on so much of the gas debt as is represented by consolidated stock, I shall not be going too far in saying that in about half the time allowed by our Act this splendid property will belong to the town, free from all incumbrance. More than that, the gas undertaking contributes large amounts to the support of institutions which cannot legally be maintained out of the rates, and in relief of rates. Thus we received in 1876-7, £5000; 1879-80, £6000; 1880-1, £12,500; 1881-2, £10,000; 1882-3, £12,000; 1883-4, £15,000; 1884-5, £21,983; 1885-6, £22,000; 1886-7, £12,500; 1887-8, £16,000; 1888-9, £16,000—total, £148,983; and our gas consumers had better and cheaper gas than almost any consumers in the kingdom. We owe for our water-works £654,796, less sinking fund, £12,779; leaving £642,017. Like the gas, this concern pays its own interest, provides a sinking fund, and contributes small sums in relief of rates—£6200 in six years; but it cannot make (it is not desirable that it should) large profits. Water being an indispensable necessary of life, as much as the air we breathe, and a powerful agent in securing and preserving the health of the town, it is not desirable to restrict proper use by high prices. The gas and water undertakings are thus shown to be profitable concerns, and could be sold any day for more than the debt we owe on them. There is, therefore, not the slightest chance of a call ever being made upon the town for any liability on their behalf; and it would consequently be absurd to class the amounts I have given of their debt with our ordinary debt as a burden upon the town."

BRADFORD CORPORATION GAS AND WATER SUPPLY.

THE WORK OF THE PAST YEAR.

At the Meeting of the Bradford Town Council last Tuesday, the reports of the several Committees of the Council on the work of the past municipal year were presented. The following are abstracts of those of the Gas and Water Committees:—

The Gas Committee reported that during the year 14,378 yards of mains and 1070 new service-pipes were laid. At the Mill Street works, 120 retorts were taken down and replaced with new ones; and the remaining 80 were repaired. At the Thornton Road works, 40 retorts were taken down and replaced with new ones; and the remaining 280 were repaired. At the Valley Road works, 220 retorts were taken down and new ones erected; and the remaining 380 were repaired. The telescoping of all the gasholders at this station has been completed; thus affording a considerable increase in the amount of storage room. At the Birkshall works, 250 retorts were taken down and new ones erected; the remaining 150 having been repaired. The whole of the foregoing were reported to be in good condition. Contracts had been entered into for the supply of 101,000 tons of coal and 20,000 tons of cannel on satisfactory terms. With respect to the gas-stove department, the Committee reported that the number of cooking-stoves sent out on hire from the opening of the department in April, 1884, to the close of the financial year was 504. The number of cooking and heating stoves sold in this period was 3592. At the chemical works at Frizinghall, 1722 tons of sulphate of ammonia were manufactured during the year, against 1753 tons made in the preceding year; the average price obtained being £11 15s. 6d., against £11 9s. 2d. for the previous year. This showed an advance of 6s. 4d. per ton, or £545 6s. on the quantity sold during the year. Of sulphuric acid, 1292 tons were produced from the spent oxide of iron, of which 1237 tons were used in the manufacture of sulphate of ammonia. The chief repairs of the works were the taking down of the largest acid chamber, and erecting a new one in its stead. The former had been in use upwards of six years; but the new chamber, being made of thicker plates, is expected to last eight or ten years. With respect to electric lighting, the Committee reported that they had adopted Mr. Shoolbred's scheme for laying down a first installation of electricity supply works on land belonging to the Corporation. It will be remembered that power has been obtained from the Local Government Board to

borrow £20,000 under the Bradford Corporation Electricity Order of 1883, in order to carry out the work. The works are now in progress; and it is hoped that they will be completed early in the ensuing municipal year. The Committee reported that during the year the lighting of the town had been efficiently kept up. All new roads and streets were lighted as soon as opened. The whole of the three-light lamps were converted into two-light lamps, of which 674 are now erected; being 74 more than last year. The number of ordinary lamps in the out-districts is 450; and the number within the district of the gas supply of the Corporation is 5283—making the total number of lamps in the borough 6407, as against 6205 last year.

The Water Committee in their report stated that the past year had been remarkable for the very exceptional distribution of the rainfall; that of the winter months being much below the average, while the fall during the early spring and summer had proved greatly in excess. On Oct. 14, 1887, the date of the previous report, the supply to both the high and low levels was restricted to 12 hours a day. This state of things continued until the 7th of November, with the exception that the supply was extended to from six a.m. to eight p.m., or 14 hours a day. After the latter date, a full supply was resumed on both levels. Owing to the dry winter months, the supply was again restricted—on the low level from Feb. 24 to March 6, 1888, to 14 hours a day; and on the high level from Feb. 24 to March 17, 1888, to the same extent. The Committee pointed out that on the 6th of March last, at a period of the year when the reservoirs are generally full, the total storage of all the works only amounted to half their full capacity. Had it not been for the unusually wet months which followed, a most serious state of affairs would have occurred. But although the storage is now in very good condition, a period of 21 months has elapsed since the reservoirs were full; and this notwithstanding the past wet summer. The connection of the high and low levels, decided upon by the Council in September, 1885, is practically complete. It may be remembered that this connection was undertaken mainly with the object of affording a better supply of water by gravitation to certain of the higher parts of the borough. The filters at Gilstead, which were brought into use in January, 1887, have remained in work continuously since that date, and have produced a marked improvement in the purity of the low-level supply. The system adopted in 1885 for the prevention of waste, and which, in conjunction with the connection of the high and low levels, was undertaken for the purpose of economizing the existing sources of supply to the greatest possible extent, so as to tide over the period which must elapse before some new scheme of extension can be brought into use, was continued with good effect during the past year. Some interesting particulars in regard to the work of the Engineer (Mr. A. R. Binnie, M. Inst. C.E.) in connection with the adoption of this system were given in the JOURNAL for Nov. 9, 1886 (p. 846). In November last, the Committee having agreed with the Corporation of Leeds to abandon the Masham source of supply, a Sub-Committee was appointed to inquire into the subject. The Sub-Committee have gone in great detail into the question submitted to them. They have inquired into two proposed schemes, have visited and inspected proposed sites, and have endeavoured to see what arrangements could be made with mill, land, and mineral owners; but questions as to the quality of the water having been raised, this portion of the inquiry has been submitted, as already mentioned in our columns, for the opinion of Dr. C. Meymott Tidy. With regard to the works, speaking generally, they have been found to continue in a satisfactory condition, and, with certain exceptions, to afford a full supply. The revenue from the sale of water during 1887 was £101,528, as compared with £97,057 in 1886, £92,153 in 1885, £91,625 in 1884, and £85,227 in 1883.

SOUTHWOLD WATER SUPPLY.—The Secretary and Solicitor of the Southwold Water Company, Limited (Mr. W. C. Tuck), has lately received from the Company's Engineers (Messrs. Smith and Pain) a report on the well which has been sunk for the supply of Southwold. They state that the supply of water therefrom is ample, and the quality good. They advise the Directors to proceed with the construction of the necessary works, which, if commenced shortly, would be ready before next summer. The Directors have held a meeting, and resolved to advertise for tenders for the erection of the works.

THE BRADFORD CORPORATION ELECTRIC LIGHTING SCHEME.—Last Friday, the foundation stone of the generating station now in course of construction for the supply of electric light to the central portion of Bradford was laid by Mr. Alderman F. Priestman, Chairman of the Electric Lighting and Gas Supply Committees of the Corporation. The object of the scheme, it may be remarked, is to supply the electric current to consumers occupying premises in Market Street, Kirkgate, and other streets in the vicinity, by means of a system of underground wires. The generating plant which is to be used for the present consists of three complete sets of boilers, engines, and dynamo machines, each equal to 150 indicated horse power, together with the other necessary apparatus for regulating the current prior to its transmission. The current will be carried from the dynamo-house by two main cables in brick or composition trenches—one along Market Street as far as the Town Hall, and the other through Kirkgate and Darley Street to the Markets and Free Library; the arrangement being such that a service can be attached at any particular point. The buildings are being arranged so that, if necessary, a rapid extension may be made, so as to meet any sudden demand. The works have been designed and are being carried out under the direction of Mr. J. N. Shoolbred, M. Inst. C.E. It is expected that they will be ready for starting early next year.

GAS v. ELECTRIC LIGHTING AT SWANSEA.—At the meeting of the Swansea Town Council last Wednesday, the minutes presented by the Special Gas Committee stated that at a meeting held on the 2nd inst. reports from the Town Clerk as to the powers of the Corporation with regard to the erection of new gas-works and the lighting of the borough by electricity were received. The Surveyor was directed to obtain such information as would enable him to fully report on the extent of works for public lighting which could be erected by the Corporation for an annual expenditure of £4060, and also as to the cost of such further works as would admit of a supply to private consumers. He was likewise instructed to report as to the desirability of adopting oil-lamps. It was resolved that, in the opinion of the Committee, it was desirable to light the borough by electricity, and that the Town Clerk be instructed to apply to the Board of Trade for a Provisional Order accordingly. At the meeting of the Committee on the 12th inst., they decided which streets in the borough should be lighted by electricity; and it was resolved that the Council be asked to invest the Committee with full powers to conclude a contract with some substantial company for the lighting by electricity of the area in question. A letter was read from the Swansea Gas Company, asking the Corporation to enter into a contract with them for the supply of gas to the public lamps for one, two, or three years at 2s. 10d. per 1000 cubic feet; and the Town Clerk was directed to reply that the Corporation were not at present prepared to enter into any contract. The minutes were adopted.

NOTES FROM SCOTLAND.

(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.

The extraordinarily fortunate position of the shareholders of the Edinburgh Gas Company, which was foreshadowed in the JOURNAL for July 3 last, has all but been realized. On Monday the shareholders met, and authorized the final distribution of the funds of the Company, in the terms of which the Directors are awarded a sum for their services, certain *employés* of the Company who have not been placed on the Corporation's pension list are provided for (not very handsomely, I am told), and the shareholders divide £100,000 among themselves. The distribution is made in the form of a bonus of £12 10s. upon each paid-up share of £25. Mr. J. K. Watson, the late Manager of the Company, was awarded a special vote of thanks for his services, which extended to over half a century. Mr. Watson has retired upon a pension of £1300 a year. The full amount allowed by the Corporations in name of pensions is £1750; so that the other pensions must be of small amount. Mr. Watson and his father were the only Managers the Edinburgh Company ever had. He deserved a vote of thanks, and the shareholders acted wisely in seeing that liberal provision was made for him in his old age; for it was owing to his energetic management that the Company was so eminently successful.

It is rather disappointing, after the Arbroath Gas Corporation had resolved to extend their gas-works, that the scheme should be placed in danger of not being carried out through the vacillation of the Corporation themselves. A fortnight ago I recorded a resolution of the Corporation not to go on with the improvements until they obtained further scientific advice. It is easy to alarm the public on questions of expenditure; and this has apparently been done in Arbroath, for on Thursday evening, at a meeting of electors, after some talk about the great cost which improving the works was likely to lead to, and the giving of advice to the Corporation as to what they should do by people who know little of the subject and have no responsibility, the electors unanimously adopted a resolution which stated that they were "opposed to the proposed extension of the gas-works, and are of opinion that any expenditure beyond what is actually imperative for the maintenance of the works is highly imprudent." Had the Commissioners either gone on with their scheme, when adopted, or had they delayed adopting it until after the elections, there is every probability that the "imprudence" which the electors now deprecate would not have come within their vision.

The inhabitants of Portsoy, in Banffshire, find themselves in embarrassment on account of the position of the gas-works. The works are nearly 50 years old; but the business is in a healthy condition. For many years it was conducted according to the wishes of Colonel Moir, who owned a great part of the undertaking. On his death, things did not go satisfactorily, through lack of a guiding hand; and his Trustees have obtained the appointment of a judicial factor, who has powers to wind up the concern. In fear of being left in darkness, a public meeting of the townspeople was held on Monday night, to consider how they could get out of the difficulty. It was reported that the output of gas had risen from 451,000 cubic feet in 1880 to in the present year—not yet completed—626,000 cubic feet. Several proposals were made, such as the formation of a limited liability Company, the adoption of the Police Acts, and then the acquisition of the Company's undertaking. Two attempts have been made to sell the concern by public auction, first at £700, and then at £500; but the only offer made was £350. At the meeting no person seemed to be inclined to become the purchaser; and a Committee was proposed to try what could be done with a limited liability Company. Nearly all the gentlemen proposed, however, declined to act; and the meeting closed without any progress having been effected.

An attempt has been made to get the Edinburgh Water Trustees to adopt the Deacon Waste-Water Meter, with a view to saving the water supply, and probably of obviating the necessity for introducing an additional supply. The proprietors of the meter offered to put down six meters as a trial; but the gentleman who was sent to make the offer I fear overshot the mark when he assured the Works Committee that, by these appliances between 7 and 8 million gallons per day would be saved. As this is nearly half the Moorfoot supply, the Trustees were incredulous; and they desired more information on the subject. A meeting of the Works Committee was held the other day, at which they had before them information from Glasgow to the effect that there the consumption had been reduced by means of these meters from 51 to 38 gallons per head per day; and the Committee, considering that the cost of fitting them on to the Edinburgh mains would be about £24,000, and also that the consumption is only 41 gallons per head per day, did not look favourably on the proposal, but delayed coming to a decision until the Engineers have reported upon the matter.

Two new reservoirs in connection with the water supply of Aberdeen were formally taken over by the Town Council on Thursday. Both are situated about two miles from the city. One at Manuofield, 160 feet above sea level, for the low district service, has a capacity of 12 million gallons; the other, at Slopefield, 300 feet above the sea level, for the middle service, holds 6 million gallons. The cost of constructing them and extending the intake in the River Dee has been £46,900. The walls of the reservoirs are built of heavy granite ashlar 16 inches thick, backed with 4 feet of rubble in cement mortar and clay puddle 1 foot thick. The bottom has been put down in three layers of concrete—the first, 6 inches thick, consisting of six of sand to one of concrete; the second, also 6 inches thick, composed of five of sand to one of concrete; and the upper layer, a thin coating in equal parts of cement and sand. The reservoirs now in operation provide about five days' supply of water for the city. At the opening ceremony, Mr. Rust advocated the extension of the storage power where the water is taken from the river. At present they cannot afford to shut off the river for much more than 24 hours at a time. Mr. Rust suggested they should have a fortnight's supply, which would enable them to take water from the river only when it was clean.

Last Saturday an additional water supply for the burgh of Jedburgh was introduced. The new supply has been obtained from several springs on one farm; the only work necessary being simply to lead the water into the existing reservoir. The cost has only been about £2300.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.

By way of supplement to last week's "Note" referring to the completion of the new holder at the Rothesay Gas-Works, I may mention that Treasurer Brown has this week reported to the Town Council that their expectations regarding the past year's working of the gas undertaking had been far exceeded, as they had made a profit of £525; while at the same time placing £100 more to depreciation of works than in the preceding year. They had reduced the price of gas during the year; and the question of granting a discount to large consumers had been left over for consideration. Mr. Mackinnon objected to the system of handing over the gas profits for the benefit of other trusts; and he held that instead of doing this they should further reduce the price of gas. He gave notice of

motion to that effect. Provost Thomson said they hoped very soon to be able to announce a reduction in the price.

The past week has brought forth quite a flood of "deliverances" on gas affairs at the municipal election meetings held in various towns throughout the province over which I have to maintain a watchful surveillance. They have been so numerous that it is absolutely impossible to overtake them all on this occasion. Hamilton is the first place that I shall deal with. At the meeting of the Fourth Ward electors on Monday evening, Mr. Rankin, while discussing gas matters, pointed out that the profits of the burgh gas undertaking for the past year amounted to £1732, being £661 more than in the preceding year. This increase arose very much from the large amount derived from residual products, which was £300 in excess of the revenue from that source in the preceding year. The coal had cost something like £100 less; while from $\frac{3}{4}$ to 5 per cent. more gas had been consumed during the year. The same meeting was addressed by Bailie Archibald, Convener of the Gas Committee, who said that he did not recollect, during all the years he had been in the town, seeing the streets better lighted than they were at present. He had obtained information as to the price charged for gas in other places; and there was none where they could say that the price at all approached theirs—that was to say, in circumstances similar to those of Hamilton. In Glasgow the price was less; but there they had a larger consumption within narrow limits. In Hamilton their district was a scattered one; and they had greater expense, besides losses from the mineral workings. He pointed out that, while they were making large profits at the gas-works, they were yearly setting aside £1000 towards the reduction of the debt. He thought they would be enabled this year again to have a satisfactory surplus; and hoped there would not be any further subsidence of the large gas-holder from mineral workings.

Gas affairs were touched upon last night by some of the Gourrock Burgh Commissioners at a meeting of the ratepayers. Provost Binnie said he was glad to inform them that the price of gas had been reduced from 4s. 7d. to 4s. 4 $\frac{1}{2}$ d. per 1000 cubic feet; and he was of opinion that when the Greenock and Gourrock Railway was opened into the town, there would be an increased consumption of gas, when they would be able to make a further reduction in the price. Bailie Lang reported that the Gas Trust was in a very satisfactory condition. The gas sold during the year ending May 15 last was 8,528,643 cubic feet; being an increase for the year of 227,610 feet. The total number of gas cookers and fires in use was 70; the quantity of gas used by them being estimated at 250,000 cubic feet with a revenue (at 4s. 7d. per 1000 feet) of about £57. On being asked if the Commissioners could not see their way to do away with the meter-rents, Bailie Lang replied that they could not both reduce the price of the gas and do away with the rent of the meters. The meters cost about £50 per year for upkeep, &c.; and he submitted a number of statistics to show that it would be better to continue reducing the price of gas than to take off the meter-rents, one of which was that there were 152 consumers of less than 4s. 7d. worth of gas per annum.

At a meeting of the ratepayers of Renfrew on Wednesday, Mr. Irving, as Convener of the Corporation Gas Committee, confined his remarks wholly to gas affairs. He said that he was not placed in a very enviable position when he became Convener of the Committee, as there was a debt of £210 to be cleared off; but being well backed up by the Council, the Committee had done a considerable amount of work during the year. New gas-pipes had been laid in various parts of the town, and the leakage of gas, which was about 22 per cent., had now been reduced to 9 per cent. (Provost Wright had previously remarked that most of the pipes had been laid so far back as 1842, and that some of them were quite honeycombed.) Mr. Irving then touched upon the new addition made to the gas-works, which, he remarked, were about 40 years old. They were almost entirely in disrepair. The retorts were all in a tumble-down state; and the gable of the retort-house was projecting in some parts about nine inches. There was another serious matter worthy of consideration. They had two gasholders, one of which was in full working order, while the other had had no gas in it for over two years. If anything went wrong with the former, the town would be left in total darkness; and it would perhaps take a month or two before the damage could be repaired. Treasurer Anderson was of opinion that they should not spend money in remodelling the old gas-works on their present site; for if they looked into the matter seriously, they would find that the removal of them to some other site out of the town would be a benefit to the community.

On the Glasgow Stock Exchange on Wednesday, the shares of the Partick, Hillhead, and Maryhill Gas Company were offered at 85s. per share; being a reduction of 3s. 6d. from the last price at which business was done. The preference shares were disposed of at 45 13s. 9d. per share—no change. On Thursday, the Glasgow 9 per cent. gas annuities changed hands at £277.

The Glasgow pig-iron warrant market has had an unsatisfactory course this week. At the close yesterday, Scotch iron was quoted at 41s. 7 $\frac{1}{2}$ d. cash buyers.

A considerable amount of activity has shown itself in the coal trade during the week; a large business having been done. Prices continue to firm up; and a general increase of wages amongst the miners seems to be almost certain.

BURY CORPORATION WATER SUPPLY.—The Bury Corporation decided last Thursday to promote a Bill in the next session of Parliament to authorize the construction of new and additional water-works, and works connected therewith; to vary, amend, or increase the rates for the supply of water within the water limits of the Corporation; to borrow additional moneys, and for this purpose to extend the borrowing powers; and to vary, alter, amend, or repeal the provisions contained in the Bury Improvement Act, 1885, for the redemption of the water-works annuities and the paying off of moneys borrowed, and to make further and other provisions with respect thereto.

THE DRAINAGE OF MARGATE.—Mr. Baldwin Latham, M. Inst. C.E., has lately reported to the Corporation of Margate on the subject of the drainage of the town. He estimates the area to be drained as 759 acres, with a population of 29,943 exclusive of visitors; increasing probably to 35,940 by the middle of August. The average rainfall amounts to about 24 inches; and more than an inch occasionally falls in one day. A separate system is not required for the high-level district. It is contemplated that the rainfall of all the high-level or gravitation district shall pass into the sewers; that of the low-level district to be carried away from the streets by the existing and improved surface-water drains. He proposes a continuous discharge, so that there shall be no stagnation either in the outfall or in the sewers of the district. The sewage is to be conveyed by direct gravitation from 629 acres and from 130 acres by pumping. He estimates the total cost at £48,000, which borrowed for 30 years (as most of it will be) can be met by a rate of not more than 9d. in the pound per annum on the district; and he reckons the cost of making the house connections at about 45s. each. Sir F. Bramwell and Sir Douglas Galton have reported upon the scheme, the general design of which, they say, appears to be satisfactory.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Oct. 27.

Sulphate of Ammonia.—A further advance in nitrate, and a continuous good prompt demand, have caused the market to harden further; and £12 is now the nearest value of prompt parcels at the various ports. There is no appreciable increase in the available supplies; and prompt lots therefore find ready buyers as they come on the market. If Germany and France are to-day less eager for near parcels, other buyers seem to be turning up; and there can be no doubt that, while the future register of nitrate prices hangs in the balance, consumers will feel more or less scared, and will endeavour to cover their sulphate requirements without waiting events. The large inquiries for spring are, therefore, not surprising. But there is a good deal of variation in the prices quoted and the business done; and it is apparently not easy to sift the actual truth of the statements made in this respect. It may be taken that to-day's approximate value for spring deliveries is £12 5s.; but while on the one hand it seems to be a fair price to be accepted, it depends on the other hand upon the nitrate movements whether still higher prices for sulphate may supervene—although, as before, beyond a certain point nitrate may cease to influence the range of sulphate values. To-day's nitrate market appears in a somewhat quieter mood; and there is rather less excitement in the sulphate trade.

LONDON, Oct. 27.

Tar Products.—This market has been somewhat languid during the past week. Benzols have not recovered the weak tendency noted for some time past. Pitch is a little more inquired for; but the price does not improve. Carbolic acid is the only product which can be said to have made any advance during the week. Prices may be taken as follows:—Tar, according to position, 17s. 6d. to 22s. 6d. per ton. Benzol, 90 per cent., 2s. 10 $\frac{1}{2}$ d. per gallon; 50 per cent., 2s. 4d. Toluol, 1s. 6 $\frac{1}{2}$ d. per gallon. Solvent naphtha, 1s. 3d. per gallon. Crude naphtha, 30 per cent., 1s. per gallon. Light oil, 3d. per gallon. Creosote, 2d. per gallon. Pitch, 12s. to 15s. per ton. Carbolic acid (crude), 3s. 6d. per gallon. Cresylic acid, 9d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 6d. per unit; "B" quality, 1s. 3d.

Ammonia Products.—Sulphate is undoubtedly better; and the demand is excellent. Considerable orders have been going out during the week; and the price may be taken at £11 15s. to £12 per ton, less discount. The prices of other products are as follows:—Gas liquor (5° Twaddell), 7s. 6d. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 2d. per lb. Carbonate of ammonia, 3 $\frac{1}{2}$ d. per lb. Muriate of ammonia, brown, £18 per ton; white, £27. Sal-ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, Oct. 27.]

Sulphate of Ammonia.—The sulphate of ammonia market is very firm, both for prompt and forward delivery. There is no abatement in the demand; and though the inquiry hitherto has been for French accounts, the Germans are now coming forward, finding that waiting tactics are likely to avail them nothing. Pressure of inquiries has resulted in Beckton raising its price to £12; and this figure is now being asked for outside makes in London. Hull values are now £11 17s. 6d.; and Leith, £11 16s. 3d. The whole position seems to hang upon the price of nitrate; and as that commodity is slowly but surely advancing, the outlook for sulphate is extremely favourable.

Tar Products.—The weakness in the benzol market noticed in last week's report still continues, but prices have not further receded; 90's stand at 2s. 10 $\frac{1}{2}$ d., and 50'90's at 2s. 4d. Solvent naphtha continues firm; and creosote is also in good demand. Crude carbolic acid (60's) remains in much the same condition as reported in our last number; and anthracene is still firm at 1s. 6d. for "A" quality and 1s. 3d. for "B." Pitch is in fair demand, but is not yet answering the expectations of sellers.

SALE OF THE LEIGH (ESSEX) GAS-WORKS.—On Wednesday last, Messrs. Edwin Fox and Bousfield sold, at the Mart, Tokenhouse Yard, E.C., the Leigh (Essex) Gas-Works. The works are very small—comprising a retort-house and coal-store combined, fitted with one single and one bench of three retorts; a purifier-shed, containing two 6-feet purifiers; and a station meter and governor house. There is a gasholder 28 feet in diameter, and a scrubber and condensers. The mains, which extend for about a mile, are of 3 and 4 inches diameter. The price of gas (which has recently been reduced) is 5s. per 1000 cubic feet. The consumers number only 35; and there are 22 public lamps, which produce nearly £50 per annum. The property was purchased by Mr. W. C. Parkinson, of Cottage Lane Works, City Road, for £720.

SUGGESTED PURCHASE OF THE KETTERING WATER-WORKS BY THE LOCAL BOARD.—At the last meeting of the Kettering Local Board, attention was called to the scarcity of water in certain parts of the town; and in the course of the discussion, the Chairman (Mr. J. Wallis) mentioned that the Directors of the Water Company were contemplating the adoption of a scheme for the improvement of the supply, recommended by Mr. T. Hawksley, under which, at an expenditure of £32,000, a reservoir of 52 acres in area would be constructed and new pumping machinery erected. Some of the members expressed the opinion that the present was an opportune time, before such a heavy expenditure as that mentioned by the Chairman was incurred, to consider the question of acquiring the Company's property; and subsequently a Committee was appointed to confer with the Directors on the subject.

THE OLDHAM CORPORATION COAL CONTRACTS AND THE ADVANCE OF COLLIERIES' WAGES.—The Oldham Gas Committee, at their meeting last Wednesday, over which the Mayor (Mr. Alderman Platt) presided, had before them a singular application from one of the colliery firms who are under contract to supply coal to the Committee. Before the letter was read the Committee were informed by the Superintendent's report that several communications had been received from Yorkshire collieries which supply coal to the Corporation, stating that it was probable they could not continue delivery in the event of a strike. The Superintendent (Mr. H. Andrew) and Mr. Alderman Hall went to Wigan to ascertain whether the Committee could be supplied from that district should such a contingency occur. The result of their inquiries was that they learned that the Wigan coal-masters would be able to deliver, having given to the men the advance applied for. The application in question was from Messrs. Pope and Pearson, Limited, of Normanton, who wrote to say that they had decided to grant the 10 per cent. advance to the men, although they were of opinion that it was totally unwarranted by the present state of the trade. They thought, however, that it was "the lesser evil of the two;" for had it been refused, a strike would have ensued, and their deliveries to the Corporation and to a few other large consumers consequently stopped. Under these circumstances, they asked the Committee for 2d. or 3d. per ton more than the contract price for their coal. The Mayor explained that the contract price was 9s. 7d. per ton, and that if they acceded to this application, and any other firms made a similar request, they would have to do the same all round. After some conversation, it was decided that the request be not acceded to.

THE RETFORD CORPORATION GAS-WORKS LOAN.—At the meeting of the Retford Town Council last Friday, the Town Clerk brought forward a scheme for saving 1½ per cent. on a loan of £30,000 for gas purposes. The Corporation have been paying 4½ per cent. His suggestions were unanimously adopted.

REDUCTIONS IN PRICE.—The *Grange Gas Company* have determined to reduce the price of gas from 6s. to 5s. 3d. per 1000 cubic feet from the 1st of January next.—The Directors of the *Accrington Gas and Water Company* have decided to make a material reduction in the price of gas, to take effect at the beginning of the new year.

THE PROPOSED WINDING UP OF THE MAXIM-WESTON ELECTRIC LIGHT COMPANY.—In the matter of a petition presented by Mr. Hugh Watt, M.P., for the winding up of the Maxim-Weston Electric Company, Limited, Mr. Justice Chitty last Saturday made an order, by arrangement between the parties, that the petition should be dismissed upon £500 being deposited by the Company in the joint names of the Solicitors for the petitioner and those of the Company, to abide the result of legal proceedings to be taken by the petitioner to establish his claim.

THE NEW WORKS OF THE CAMBRIDGE WATER COMPANY.—Last Tuesday afternoon, the ceremony of laying the memorial stone of the new works which the Cambridge Water Company are constructing at Fulbourn, as an auxiliary of those at Cherry Hinton, was performed by the Rev. Dr. Perowne, Master of Corpus Christi College, the Chairman of the Company. The works, which have been necessitated by the increasing population of the district, were commenced last November. The buildings comprise an engine-house, 42 feet long by 30 feet wide, in which are two engines, each of 40-horse power, with three boilers of the newest construction, as well as coal-stores, smith's shop, &c. The wells, at the present time, are capable of delivering 2 million gallons of water a day. It is expected that the buildings will be completed and all the necessary engines laid down in about twelve months' time. The works have been designed by the Company's Engineer (Mr. T. Hawksley), and carried out under the supervision of the Manager (Mr. W. W. Gray).

PROPOSED CONSTANT WATER SUPPLY FOR WIMBLEDON.—At the meeting of the Wimbledon Local Board on the 17th inst., the Clerk (Mr. W. H. Whitfield) reported that a deputation appointed by the Board waited upon the Engineer of the Lambeth Water Company (Mr. J. Taylor, M. Inst. C.E.) with reference to the question of a constant water supply in South Wimbledon. The Company proposed to introduce a constant supply experimentally in certain parts of the parish within their district. They would then see how far they were able to deal with the difficulties that arose under their existing statutory powers. There seemed to be every ground for supposing that the Company would be able fully to deal with the difficulties, and prevent the misuse and waste of water. If this was done, he believed there would be no impediment to their supplying the whole of the lower part of the parish constantly. The Chairman (Mr. J. Townsend) thought the Company had met the Board very satisfactorily. They offered to make the necessary experiments with a view to ascertaining their position; and if they found there was not much waste from the constant supply, they would be prepared to adopt it generally.

LEEDS CORPORATION WATER SUPPLY.—On Monday last week the Water Committee of the Leeds Corporation visited the Blackmoor Tunnel works, which are being carried out by the Borough and Water Engineer (Mr. T. Hewson, M. Inst. C.E.). It is now six months since the works were commenced; and although it will take close upon two years to complete the scheme, satisfactory progress has so far been made. The laying of the new line of 42-inch pipes from the mouth of the old tunnel at the Seven Arches to the filter-beds at Weetwood has been completed; and water is now being carried between these points by this line. The line of 42-inch pipes and the old line of 40-inch pipes are capable together of conveying all the water that it is possible to collect from the Washburn; so that this section of the water-works may be said to be complete. The laying of the additional pipe-line, by increasing the means by which the water can flow to the filter-beds, has reduced the quantity passing through the old tunnel; the depth at the point of discharge being about 15 inches instead of 5 ft. 3 in., as was formerly the case. The effect of this reduction of the depth of water in the old tunnel has been to do away altogether with the leakage of the water through it into the new tunnel; thus saving the water, and enabling the new work to be carried on under more favourable conditions.

THE WORCESTER CORPORATION AND THE GAS COMPANY'S ACCOUNTS.—On Friday last, at the meeting of the Worcester Watch Committee, the accounts of the Gas Company for the half year ending June 30 last were produced. Mr. Corbett said he had gone through them, and the result of his investigations was to show that the Council had been justified in the policy which they had pressed upon the Gas Company, and which the Company had adopted. The increase in the quantity of gas consumed in 1888 was 7 million cubic feet, or 5 per cent. on the total consumption; showing that there was a steady progressive increase, to which attention had been called on former occasions. The result had been that although during the last two years the discounts allowed by the Company had been much increased, the net income had not appreciably diminished. The net sales in 1886, before the increase of these grants, was £20,100, and in 1888 they amounted to £20,000; so that, although there had been an increase of discounts, which had given the public an advantage of £1600, the net income of the Company from the sale of gas had only dropped £100. There had been, as anticipated, some slight falling off in the profit from residuals; but this had not been so much as the Company at the time thought likely. The net result of all the figures had been that the income, in spite of increased discounts and the diminution in the value of residuals, only showed a falling off of £400.

SALES OF SHARES.—A part of a King's share and 21 £100 new fully paid-up shares (returning a dividend of over 12 per cent.) in the *New River Company* were sold by Messrs. Edwin Fox and Bousfield, at the Mart, Tokenhouse Yard, last Wednesday. The first eleven lots disposed of each consisted of a 96th part of a King's share, and produced the following prices:—1½ lots, £880 each; one, £885; three, £890; two, £900. The next lot—a 100th part of a share—realized £900. The succeeding three lots each comprised a 120th part of a share; and fetched £700 each. Seven lots, consisting each of a 130th part of a share, were sold as follows:—One lot, £620; four, at £625; one, at £630; and one, at £635. The 21 new shares were disposed of at almost uniform figures—Eight realizing £353 each; three, £354; one, £355; four, £356; five, £357.—On the previous day, Messrs. Nicholson, Greaves, and Barber sold a number of the newly-issued shares of the *Sheffield Gas Company* at premiums ranging from £4 2s. 6d. to £4 10s. each.—On the same day, six £10 shares in the *Brechin Gas Company* were sold by public auction; and the prices realized ranged from £35 to £35 2s. 6d. per share.—Last Wednesday, Messrs. Boulter and Cooper sold by auction, at Malton, 41 fully paid £10 shares, and 20 shares on which £6 had been paid, in the *Malton Gas Company*. The former realized £25 to £25 2s. 6d. each; the latter, £15 10s. to £16 10s. each.—Last Friday, £144 "A" stock in the *Farnworth and Kearsley Gas Company* was sold for £365.

GUERNSEY WATER-WORKS COMPANY, LIMITED.—This Company was registered last week with a capital of £40,000, in £5 shares, to carry on in the island of Guernsey the business of a water company in all its branches, and also the manufacture and sale of ice and aerated waters; and to acquire a concession granted by an Act of the States of the island, sanctioned by Her Majesty in Council on Nov. 23, 1857, and any other concession granted, or to be granted, in respect of the water supply of the island, or any extension thereof.

OSWESTRY WATER SUPPLY.—The Oswestry Town Council have finally adopted a scheme for an improved water supply, prepared by Mr. H. Rofe, C.E. It is intended to construct a reservoir to contain 24 million gallons of water on land purchased at Penygwly. Tenders were received some time ago for carrying out the work; but, as they all exceeded the Engineer's estimate, amended plans and specifications were prepared, and fresh tenders invited. At a special meeting of the Council, held last Thursday, the Engineer recommended that the lowest tender—that of Messrs. J. Jevons and Sons, of Dudley, for £9939—be accepted. The recommendation, after a long discussion, was unanimously adopted.

PONTEFRAC TOWN WATER SUPPLY.—Last Tuesday, a meeting of the rate-payers of Pontefract was held in the Assembly Rooms to consider the proposed new water supply. The Chairman (Mr. Robson) stated that all agreed a better supply of water was needed; but the question was which would be the cheapest and best scheme to adopt. Mr. W. R. Maud spoke at some length, and gave the reports of analysts on the water at present used. He proposed—"That this meeting, while recognizing an additional supply of water to be necessary, believes the Roall scheme to be unnecessary, expensive, and doubtful." The Mayor (Mr. Alderman Mathers) and others spoke in favour of the Roall scheme, and met with some opposition. The resolution rejecting the Roall scheme was carried by a great majority.

THE PROPOSED ELECTRIC LIGHTING OF EXETER.—At the meeting of the Exeter Town Council last Wednesday, a report presented by the Special Committee on Electric Lighting was considered. The Committee had opened tenders, on a seven years' basis, for lighting by electricity the selected district. The Committee pointed out that the lowest tender represented a cost of £1486 17s. 6d. per annum, while the present cost of lighting the same district by gas was, according to the Surveyor's report, £666 11s. 8d. The total illuminating power of the existing gas-lamps would be 2000 candles, while that of the electric light would be 32,000 candles. Having regard to the large increase in the cost, as compared with that of gas, the Committee did not recommend that any of the tenders should be accepted; and in this the Council concurred.

chokes respiration, and blurs the visual aspect of outer objects. Lights are almost powerless to penetrate this mixture of mist and smoke. Scarcely can the wayfarer see one street gas-lamp at a time; he certainly cannot see the second. Drivers of vehicles are compelled to lead their horses and make sure of their course by observations of the kerb of the street pavement; and when they have to negotiate a wide crossing they must trust to Fate for getting to the corner for which they aim. The usual street noises are either hushed or strangely muffled and changed; but the improved acoustic properties of the thickened atmosphere are witnessed to by the startling distinctness of sounds usually unheard or diminished. All this, be it remarked, is characteristic of an old-fashioned yellow fog, which strangled our forefathers in the streets of London just as it does their successors to-day. The “London particular,” however, is no longer confined strictly to the Metropolis. The growth of towns in different parts of the country has prepared conditions as favourable to the development of the densest kind of fogs as used to be found in London alone; and consequently at the present day Manchester and other places are occasionally plagued with fogs which do not yield in vileness of character to anything that London can show. The other variety of fog, which we have already remarked as distinct from this deadly mixture of antique repute, is not so thick upon the ground, but is much blacker overhead. It does not so acutely affect the eyes or the lungs, and in this respect is more endurable; but no words can adequately describe the gloom where it enthrones itself on the housetops. To look up towards what should be the open sky is like gazing into a coal-cellar. Wayfarers flit along the streets like disembodied spirits; and vehicular traffic is carried on as though in a cavern. The general aspect of the streets and shops is much the same as that presented on a murky, wretched night. The window-glass seems dirty, and the gas looks bad, yet comfortable, for everybody hastens to light up in order to dispel the unnatural dusk. If a fog of this kind were to happen at night, it would not be very noticeable except for the deadness of the air, which renders breathing unpleasant, although not in the same way as a pungent yellow fog. The influence of the invisible carbonic acid, which is probably present in abnormal proportion in the stagnant air, is sensibly felt by all animate beings. This and the blackness at midday combine to make London in a fog of the kind now under notice a place to be shunned during the continuance of the infliction. Fortunately these fogs are frequently very local, and the slightest movement of the air clears them away.

Dwellers in London during the past few weeks have had every reason to regard the smoke and fog abatement movement in which their Lord Lieutenant designate, the Duke of Westminster, took such a lively interest some years since, as the dearest of failures, so far as concerns its primary object. In subsidiary aspects, the agitation undoubtedly effected some good while it lasted. It demonstrated anew, if such demonstration was needed, the connection between coal smoke and the worst characters of town fogs. It placed a definite ideal before the designers of domestic fireplaces; and it assisted to make gas cooking-stoves popular. If this popularity had depended wholly on the recommendation that such stoves do not contribute to make fogs obnoxious, however, it is only too probable that human selfishness would have soon forgotten it. People will consult their own convenience and profit, whatever missionary enthusiasts may say to induce them to take loftier views. Consequently, when the gas cooking-stove is introduced into a household, although its admission may have been procured or assisted by the exhortations of those whose aim was smoke prevention, its continuance will depend upon its economy, efficiency, and practical convenience in action. Good intent does not excuse indifferent performance in these matters; and this is the reason why the application of the Smoke Prevention Acts is so troublesome in the case of factories. The dilettante smoke abatement agitators knew nothing whatever about the economy of steam-raising and general factory furnace work; and accordingly they made themselves very ridiculous, and damaged their own cause, by the extravagance of their assertions respecting the money benefit of smoke-preventing appliances. Even when the law relating to smoky chimneys is as impartially enforced as it is in London, it is difficult to do justice between the manufacturer and the public. In very many instances, of course, the adoption of coke for direct-acting furnaces, and the supersession of these by gas-furnaces, would mitigate the nuisance which brings the factory-owner before the

THE JOURNAL OF GAS LIGHTING, WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, NOVEMBER 6, 1888.

INVINCIBLE FOG.

WHAT has become of the well-meaning people who banded themselves together a few years ago for the purpose of conquering and driving out the curse of English town life during the long winter months—smoky, choking fog! Alas! the Smoke Preventionists have gone, but the fog remains. They have retired absolutely worsted from the encounter with the foul foe, who still holds possession of the field. As these lines are being written, London lies literally gasping for breath under one of the blackest and most persistent fogs that have ever visited the valley of the Thames. It is a perfect example of that variety of the London fog which has been distinguished of late years from the traditional “pea-soup” fogs so clearly described by Dickens in his tales of London life. We still get too many specimens of this type of fog to forget what it is like. It is the thickness of what has to serve for air, which makes the eyes smart and weep,

Magistrate; but very often the administrator of the law is appealed to in terms which he can hardly resist. What is the Magistrate to do when a manufacturer shows that he has spent a great deal of money on various devices warranted to protect him from the operation of the law, and has found little or no relief from any of them? We do not say that the law forbidding the production of smoke from factory furnaces cannot or should not be enforced, but only that it is not so easy a matter as making a speech upon the subject. There are many factories in London and other places at present working without polluting the air with smoke; but we are not aware that any economy in the consumption of fuel in these factories is directly traceable to its suppression. Fear of the smoke inspector induces careful stoking; and this is something to the good, smoke or no smoke.

After all has been said and done, however, with reference to the abatement of the smoke from factory chimneys, the fact remains that it is the domestic hearth that is the chief offender in the matter of aggravating town fogs. London, with the other large towns of Great Britain that have established fogs of their own after the London pattern, grows bigger every year. Each successive winter lengthens the distance to be traversed by the prevailing winds between their first entering what may be called the town on one side and leaving it on the other. The influence of the radiation of roads, pavements, walls, and roofs, replacing that of green fields and gardens, extends every year. The cultivation of the rose, and the successful growing of fruit on trees freely exposed to the air yearly retreat to more distant suburbs. The hill covered with villas that last year saw the fog creeping round its base for the first time, is submerged this year. The friction of the light autumn winds against so many miles of chimneys and roofs tires them out before they have half crossed the desert of houses, and prevents them from reaching the meadows beyond. So the interior of the town is buried in fog, even though the outskirts are clear, until a stronger breeze arises and wafts the dingy pall away, or the rain washes it down, blackening the fleeces of sheep even as far away as the Sussex downs. There is little hope of deliverance from this state of things. The gas-stove does good, doubtless, as far as it goes; and coke is useful in its way. It is not easy, however, to see what can remedy an evil so great, so persistent, and so deep-rooted. Nature and man have co-operated in creating it; and it seems idle for one partner alone to think of undoing the joint work.

REDUCTION IN THE PRICE OF GAS BY THE CHARTERED COMPANY.

FOLLOWING the sitting of the Court of Directors of The Gas-light and Coke Company on Friday last, the Secretary and General Manager (Mr. J. Orwell Phillips) sent out an intimation to the effect that the price of common gas in the Company's district would be reduced to 2s. 6d. per 1000 cubic feet as from the beginning of the new year. We sincerely congratulate the Directors and their able General Manager upon this announcement, and have not the slightest doubt that the effect of the reduction upon the Company's business will be all that they can desire. The intelligence has been very well received by the London newspapers; and in coming down so handsomely in their selling price, without any pressure from outside, the Directors of the Company have testified to their wish to retain the patronage of the public, as well as taking the best means for securing it. It will be some time before the publication of the accounts of the undertaking for the current half year permits any one to ascertain the circumstances in connection with the revenue account which have enabled the Directors to make this great sacrifice; but it is open to an observer to imagine that the returns for the past quarter and the prospects of the future must have been very reassuring. However this may be, the Directors may be certain of the best wishes of all sincere friends of the gas industry of the country for the success of the enterprise which they have now displayed. They have done a bold thing and an unexpected; but they have put their hands to nothing that, with careful management and ordinary good fortune, can be said to surpass the limits of prudent administration.

THE END OF THE COAL STRIKE.

THE anticipations expressed in these columns with regard to the issue of the coal-miners' strike have been justified by the result. The crisis is over, and the men have won. This is the sum and substance of the story, although there may be a few isolated cases which constitute exceptions to the general rule of resumption of work at an advanced rate of wages. The

price of coal has slightly risen, but the attempt of the retail dealers to make use of the fact of the threatened strike for the purpose of putting up their rates by 2s. and 3s. per ton has failed. A sudden rise in prices coincident with the beginning of a general strike was only to be expected; but on the whole the movement has succeeded in its primary object without very greatly disturbing trade. Those journals which, in the supposed interest of the coal-owners, were most emphatic in declaring that the advance of wages demanded by the men could not be granted, and must accordingly be resisted to the utmost, have had to "sing small" since the masters, after making a vain show of firm resistance, gave way one after another rather than keep the pits idle. It must be very galling to an advocate to lose his case through the surrender of his client; but in this instance there was nothing else for it. It is to be hoped that the men will not be misled, by the ease with which they have won their battle, into thinking that they can do the same again whenever they choose. There are times, of course, when it would pay owners better to shut up their pits than to work them at an additional charge of 10 per cent. for wages; but the men's advisers probably know pretty well how the facts really stand at any time, and are not likely to push matters to extremities without making tolerably sure of their ground. Those owners are wisest who have met the demands of their men most fairly and openly. Some who have endeavoured to pare away the benefit of the higher rate of pay by insisting upon additional conditions, have had to give way after all; but in such cases the victory of the men has become a triumph which neither side is likely to regard in the right light for a long time to come. There is nothing more to be said upon the subject, except to recognize the good humour, or at least absence of riot and outrage, that has distinguished this last from some other industrial campaigns of the kind. True, it did not last long enough for the men to be driven desperate; but, as the record stands, one would fain hope that it may be taken as an indication that the spirit which reached its greatest development during the cutlers' strikes, in the personality of Broadhead at Sheffield is no longer extant in the district which has been the scene of the coal-miners' strike of the present year. The men have probably learnt, from extended experience and improved tuition, that wages questions, being essentially economical, are susceptible of economical treatment and solution, and that the murder of a mine manager or two is not the best way to improve their own position.

THE DINSMORE GAS PROCESS.

THE watchful chronicler of gas engineering progress passes in review all sorts of devices for increasing the yield or decreasing the cost of illuminating gas from coal, and is frequently amused at the performances of inventors, who will persist in repeating, with more or less variation, the attempts of their predecessors to "revolutionize"—that is the favourite word—the ordinary process of carbonization. The latest of these schemes is that of the Dinsmore Gas Company, Limited, a Liverpool speculation started to exploit the invention of Mr. Dinsmore, one of whose patent specifications was published in the last number of the JOURNAL. The report of an extraordinary general meeting of the Company is given in another column; so that, to all appearance, the undertaking is a live concern, the promoters of which intend to appeal to the public for means to carry out their gas-making projects. It is therefore time to utter a word of caution. Essentially it is a process for increasing the yield of gas from coal subjected to destructive distillation by the expedient of returning the tar to the same action, with a view to converting it into gas. This is done by a system of inclined pipes in which the tarry vapours are carbonized instead of being immediately led away as in the ascension-pipes of ordinary carbonizing plant. By this means it is claimed that from Lancashire coal 1500 cubic feet more gas per ton can be obtained than in the usual way, while the illuminating power of the gas is raised from 16 to 22 and even 28 candles. Now, in the first place it is necessary to ascertain what are the capabilities of the raw material from which this additional yield of gas is said to be derived. It admittedly comes from the tar, and hence must be supposed to be in the tar. But suppose it can be proved that the tar does not, and cannot contain anything of the kind? What then becomes of the process? In the JOURNAL for Feb. 2, 1886 (p. 200), will be found a paper upon the "Enrichment of Coal Gas by Certain Hydrocarbons," read by Mr. G. E. Davis, F.I.C., &c., before the London Section of the Society of Chemical Industry, which opens with an examination of this very idea of attempting to make gas from coal

tar. We shall not quote from the paper, for our gas engineering readers know all about the fate of anybody who tries to turn tar into gas; and those who do not—among whom must apparently be classed Mr. Dinsmore and his friends—may most profitably be referred to the text. This paper simply cuts the ground from under Mr. Dinsmore's feet. It is superfluous to discuss the points of his apparatus when the raw material upon which it is designed to operate is known to be unsuitable for the purpose intended. It is hopeless to expect that a time will ever come when people will exercise common-sense precautions in making sure of their facts before lending their names to projects which the first comer with any knowledge of the subject can upset. Hence we do not look for any early release from the duty of keeping watch upon the entry of delusive schemes into the range of the interests to which we are specially devoted, and from the unpleasant task of bearing testimony to the folly and rashness, of their promoters. This Dinsmore example is merely the revival of a notion, the hackneyed nature and hopelessness of which would have been revealed upon the merest inquiry in the right quarters. The Chairman of the Company knows enough to confess that "the idea is 'not a new one,' and goes on to declare that "it had 'never been satisfactorily carried out'—to which we take the liberty of adding, "and never will be."

MR. JAMES SOMERVILLE ON GASHOLDER GUIDING.

GASHOLDER construction is all the talk just now among gas engineers on both sides of the Atlantic. The Southern District Gas Managers will discuss the question of the guide-framing of gasholders, upon the invitation of Mr. George Livesey, on Thursday next; and meanwhile we may draw attention to a remark made by Mr. James Somerville, of Indianapolis, in the course of a paper contributed by him to the American Gaslight Association at their recent congress. The paper was, like its author, more useful than pretentious; being made up of observations upon points of gas-works management that had occurred to the writer in the course of a long and fruitful experience. It was, in short, a sample of just such table-talk as an experienced engineer might retail at any time for the entertainment of his fellows or the instruction of a young man in whom the speaker felt interested. Among other things, the paper contained the following pregnant statement:—

My observation of the daily working of holders leads me to this conclusion: Whenever trouble has occurred, it can invariably be traced to one source—viz., the weakness of the bottom curb. We have a holder 130 feet in diameter and only 16 feet in height. Why it was built of these dimensions I cannot tell. It is strongly trussed. The centre of gravity is nearer the top than the bottom, so that a little gale of wind invariably tipped it over. Indeed, I have seen it at right angles—one side jammed into the tank, the other high in the air. . . . I found that every roller was out of place, and the bottom curb badly bent in. I substituted wrought iron for cast wherever it could be done with the rollers, and put a heavy log chain or brace against them on the inside, fastened to the curb, and jammed the rollers tight against the guides. I filled it up again, and no one was more surprised than myself to see how steady the holder has worked ever since—now nearly ten years ago. . . . There are twelve columns to the holder; but as for keeping it steady, it might as well be without them.

This is the strongest possible evidence in support of the position taken up by those who declare that the stability and steadiness of a gasholder chiefly depend upon the bottom rollers. As we have stated this view, it is briefly expressed in the remark: "Take care of the bottom guiding of a gas-holder, and the top will take care of itself." The saying does not, of course, contain the whole truth; but it conveys a very useful sample of it, and indicates the direction in which more may be obtained.

THE London correspondent of the *Manchester Guardian* states that a "Syllabus of Policy" for the new London County Council has been issued by a Liberal Association. In view of the coming elections, the matter is of interest. First in importance is placed the efficient and economic use of the public funds; and among the other subjects mentioned as requiring special attention are the abolition of the coal and wine duties, and the control of the gas and water supply. It is specified that the undertakings of the Metropolitan Gas and Water Companies are to be acquired at an "equitable valuation."

INVESTORS in gas and water stocks will see, by our advertisement columns, that excellent opportunities are now being afforded them for increasing their holdings in these substantial securities. Messrs. Thurgood and Martin will, early next month, offer for public competition, by order of the Royal College of Surgeons, £24,780 of stock in the Crystal Palace District Gas Company, and 375 fully paid £6 shares in the same undertaking (forming a portion of the bequest to the College by the late Sir Erasmus Wilson); and the Directors of the East London Water Company are inviting tenders for £53,000, being the third portion of the new 4½ per cent. perpetual debenture stock of the Company.

Water and Sanitary Affairs.

THE scientific interest that attaches to the deep boring of the Southwark and Vauxhall Water Company at Streatham has been the occasion of a recent article in *The Times*, in connection with a forthcoming treatise by Mr. William Whitaker, of the Geological Survey, on the geology of London. We have adverted on more than one occasion to the peculiar character of the Streatham well, in reference to the chance of finding the lower greensand, and the possibility of some further light being thrown on the question whether coal measures exist at a workable depth in the south-east of England. The Streatham well unfortunately demonstrates the absence of the lower greensand at that spot. This is somewhat at variance with the result achieved at Messrs. Meux's brewery in the Tottenham Court Road, where the lower greensand was found at a depth of 1000 feet from the surface. But 70 feet further down an entirely different formation made its appearance—belonging to the Devonian series. Water could not be obtained in any quantity; and the further prosecution of the boring was abandoned. Even the brief encouragement of going down through some 60 or 70 feet of the lower greensand has been wanting at Streatham, although a very useful supply of water is available from the upper strata, and will probably be turned to account. From the gault, the boring tool has passed into the forest marble beds of the lower Jurassic limestone. Mr. Whitaker calculates that the Jurassic rocks of the Streatham well are not likely to be very thick; and the point of interest consists in knowing what underlies them. A little more boring may help to solve one of the greatest problems in English geology. At Meux's brewery there was a plunge from the rocks of the secondary formation into a depth below the carboniferous strata. The intruding rocks of the primary formation were found inclined at a high angle, though in what direction does not appear. On the slopes of the ridge would lie the rocks of a later period; and among these might be found the beds belonging to the actual coal measures. The presence of the primary rocks at about 1000 feet from the surface has been proved by more than one deep boring in and near London. Above thirty years ago, Mr. Godwin-Austen elaborated his theory as to a connection between the coal-fields in the west of England and those of Belgium and the north of France. Well-considered reasons were shown for believing that the coal measures of a large portion of England, France, and Belgium were once continuous, and that the present coal-fields were merely fragments of a great original deposit, subsequently broken up in two directions prior to the deposition of the secondary rocks. Sir Roderick Murchison took a different view of the case; but the theory has nevertheless been countenanced by many distinguished geologists, and every deep boring in or near the valley of the Thames excites renewed hopes that the Godwin-Austen theory may be verified. It is a question of "striking ile." But the Directors of the Southwark and Vauxhall Water Company cannot devote the money of the shareholders to a problematical search for coal, however interesting such an enterprise might be from a scientific point of view. This principle was emphatically expressed at the recent meeting of the shareholders, by the Chairman, Alderman Sir H. E. Knight; and there is a risk that the boring, which has now gone down more than 1160 feet, will be stopped, unless the public appeal made by Mr. Whitaker for a special fund receives a prompt and satisfactory response. Collieries and iron-works in Kent and Sussex are not altogether desirable; but they would nevertheless add to the wealth of the nation.

After setting in motion sundry complicated and curious forms of law in connection with a criminal indictment directed against the Staines Local Board for "causing or suffering" sewage to flow into the Thames, the Conservators of the river find themselves foiled; and the sewage of Staines, so far as the town has any sewers, continues to flow as heretofore, except that henceforth it will be with the sanction of Her Majesty's Judges in the High Court of Justice. The legal considerations which have led to this result will be found in our report of the case, as argued in the Queen's Bench Division, and decided upon, last week. It will probably be news to many people to learn that it is possible not only for owners of house property to have a prescriptive right to use certain sewers, but for the Sanitary Authority of the district to be under no responsibility to prevent the said sewers from discharging their contents into the nearest river. It may be asked, What is the good of our Rivers Pollution Prevention

Act, or the Acts which give authority to our Conservancy Boards, or the Acts which constitute our local Sanitary Authorities, if a right to drain houses into sewers discharging into a river is to be recognized after this fashion in the Courts of Law? It is said, in respect to Staines, that the Conservators should take proceedings against the individuals who use the sewers, and not against the Local Board; the latter being powerless in the matter. But while the Local Board plead that they have no power to prevent the drainage of certain houses from entering the sewers, the owners of the houses may plead that they are not responsible for the destination of the sewage after it has once left their premises. They may contend that it is the duty of the Local Board to intercept the sewage and keep it out of the river. It is here that the practical part of the question interposes itself. There are three sewers at Staines discharging into the Thames; and it seems out of all reason to ask the owners of the house property connected with these sewers to deal with the sewage *en masse*. That is the function of the Local Authority, created for the very purpose of providing proper drainage for their district. If proceedings taken against the inhabitants are so far successful as to shut up the sewers, the only remaining resource is that of cesspools. Does the ancient use of a cesspool confer a vested right? If a man gives up his ancient cesspool, has he a claim to compensation? It is understood that there are peculiar difficulties which have hitherto prevented the adoption of a general system of drainage for Staines. But is Staines so exceptionally situated that it must differ from all the other towns in the kingdom? The London Water Companies are paying to the Conservators many thousands of pounds per annum in order that the Thames above their intakes may be protected from pollution; and yet certain sewers in the town of Staines are to be allowed to discharge into the stream. How was the drainage of London effected? How many houses had long enjoyed the privilege of draining into sewers which discharged into the Thames within the Metropolitan area? The main drainage works of the Metropolitan Board simply intercepted the flow, and carried the sewage off to Barking and Crossness. The recent judgment in the Law Courts has apparently been cramped and twisted by the terms of the "special verdict" to which it had particular reference, and by which its view was necessarily limited. The rusty machinery of an antiquated procedure was brought to bear upon a modern emergency, with which it was utterly unable to deal. The Staines sewage must be kept out of the river somehow; though how many years the lawyers will require in order to find out the proper way, seems beyond present calculation.

We learn from one of the Halifax local papers that Mr. W. Carr is going to Trinidad, under a two years' engagement, to superintend the erection of gas-works there.

At a special general meeting of the members of the Society of Telegraph Engineers and Electricians to be held next Thursday, a resolution will be submitted to change the name of the Society to "The Institution of Electrical Engineers." There is little doubt that the proposition will be agreed to; inasmuch as 837 members out of the 846 who have replied to the circular addressed to them on the subject early in the year have expressed approval of the change.

Our contemporary the *Builder*, referring to the judgment of Mr. Justice Stirling, in the proceedings taken by Mr. Lewis against the Weston-super-Mare Local Board, reported in our columns last week, expresses the opinion that the case will go to a higher tribunal. The point upon the construction of section 16 of the Public Health Act was as to the meaning of the word "necessary"—that is to say, whether it meant "desirable," or whether it meant "absolutely necessary." The Local Authority, it will be remembered, desired to have a pipe laid through the garden of the plaintiff. This was not the only course open to them; but, on the other hand, it was the most desirable one. His Lordship decided that the word "necessary" in the Act meant "desirable," or, as he expressed it, "necessary for the efficient discharge of the duty in the way which is most for the public interest." Our contemporary remarks: "There is much to be said on both sides; and it is always difficult to construe such a word as this, since different minds look at it from all kinds of standpoints. We are somewhat inclined to think, however, that the construction adopted by Mr. Justice Stirling gives almost too much latitude to public bodies, and scarcely safeguards private interests enough. Private property should not be interfered with by public bodies if it can possibly be avoided. According to this decision, it would seem allowable to cut up a garden by laying water-pipes beneath it, if, by so doing, a slightly shorter route could be taken, and a few pounds thereby be saved to the community; for, although such a method of carrying out the work would not be absolutely necessary, it would clearly be for the public interest to save money."

Essays, Commentaries, and Reviews

GAS AND WATER COMPANIES IN THE STOCK MARKET (For Stock and Share List, see p. 817.)

THE condition of the Stock Exchange markets during the past week has been on the whole rather quiet and dull; and they offer no feature of any interest. It was thought to be quite within the bounds of possibility that the Bank of England rate might be lowered on Thursday; but an unforeseen demand for gold kept it up. The Gas market has been brisk; and the "bears" have been active. A "boom" in electrics is being worked. No matter what the undertaking may be, so long as it is something electric (or even its title suggests electricity), that will do; and, of course, as a co-ordinate of the boom, gas is to be worked down. The run is being principally made against the Metropolitan Companies; but others share in it to a less degree. Whatever may be in the store of the future, at present the Gas Companies are not suffering. We believe that the ten months accomplished of 1888 have been for the London Companies a period of prosperity far above recent annual averages; and if the remaining two months should be proportionate, the accounts for the full year will be remarkable. They will be especially gratifying to those who keep cool and buy stocks when they are being run down, as now. It is significant, as indicating the estimate of the position formed by the Directors of The Gaslight and Coke Company, that they have already notified their intention to reduce the price of their gas by 3d. per 1000 cubic feet at the end of the year. This means a voluntary sacrifice of £200,000 off the annual gas-rental on its present scale. The result of the week's operations has been to lower Gaslight "A" 4; South Metropolitan "A" and "B," 2½ each; and Commercial old, 1. There has, however, been going on quietly during the week some good steady buying of some of these stocks at the reduced figures; and, though it is always difficult to forecast the next move (especially if people lose their heads and throw stock on the market), we should not be surprised to see the pendulum swing the other way. There has been a fair amount of business doing in Water, at average figures; but nothing to call for remark.

The daily operations were: Moderate business in Gas on Monday. Gaslight "A" and British fell 1 each. South Metropolitan "B" buyers were 2 lower. Water was quiet and unchanged. On Tuesday, Gas was rather more active. Commercial old receded 1; and Gaslight "A" and British fell 1 more each. Nothing in Water. On Wednesday Gas was very quiet; but knocking down quotations continued. South Metropolitan "A" fell 2½; "B," 1½; Gaslight "A," 1; and Imperial Continental, 1. Thursday, being the 1st of November, was a holiday. On Friday, Gas was very active; dealings being freely distributed through the list. Gaslight "A" was done at 24½—the lowest mark of the week; and the quotation fell 1. Water was brisker; and Southwark ordinary rose 1. On Saturday, Gas was a little better; and Gaslight "A" marked 24½ at the close. But business was very quiet. In Water, Southwark ordinary rose 1 more.

ELECTRIC LIGHTING MEMORANDA.

ANNUAL MEETING OF THE EDISON AND SWAN COMPANY—ALDERMAN F. PRIESTMAN ON THE BRADFORD ELECTRIC LIGHTING SCHEME—THE WHITEHALL ELECTRIC LIGHTING STATION—THE COST OF ARC LAMPS IN CANADA.

THE Edison and Swan United Electric Light Company held their annual general meeting on the 22nd ult.—the Chairman (Mr. J. S. Forbes) presiding. The profit and loss account for the year, as mentioned last week, showed a credit balance of £25,123, whereas that for the previous year was £16,221. According to the statement of the Chairman, the Company have laid out upon patents, goodwill, preliminary expenses, and old losses on working, the respectable sum of £304,028. The Chairman explained that when the Company began they for several years made losses upon revenue account; and these were all added together and entered against the time when they could be wiped out by profits. This time has come; and at the last meeting Mr. Forbes was able to assure the shareholders that the Company are "fairly on their legs as a money-earning concern." If the Company were absolutely free of legal troubles, it appears from this statement that they might honestly distribute this profit of £25,000 for the past year's working, because the Chairman assured the proprietors that this is the amount remaining clear after charging the concern with every proper outlay, and being somewhat liberal in the matter of depreciation. Unfortunately, however, there is the pending litigation with the Brush Company to be considered; and, having regard to the proverbial uncertainties of the law, the Chairman recommended, and the proprietors agreed, not to distribute this money, but to keep it in hand in readiness for any emergency. Coming to the question of the progress of electric lighting, Mr. Forbes somewhat cynically remarked that while the Company had come down from their early aspirations, and confined themselves to the humble task of lamp-making, the Directors were "very delighted to see other people embarking their capital and energy in the installing work." In other words, having abandoned the fascinating but disappointing work of gold-digging, Mr. Forbes is content to play the less conspicuous but more profitable part of sutler to the gold-diggers' camp. The meeting was more harmonious and satisfactory than are most gatherings of the shareholders of electric lighting companies; thanks probably to the adoption of the policy defined by the Chairman.

Alderman F. Priestman, of Bradford, as was mentioned in the

JOURNAL last week, has recently laid the foundation-stone of the Corporation electricity works; the occasion being observed with some ceremony. There was a meeting of members of the Corporation and leading townsmen, who were addressed by the Alderman (who is Chairman of the Gas Committee) upon the policy of the Corporation respecting the undertaking in question. He stated that the reason the Corporation had decided to lay down electric lighting plant was their determination to keep all such undertakings in their own hands. They will no more have an electric light company among them than they would suffer an independent gas company; and if the townspeople want electric lighting, it is the Corporation to whom they must look for it. This view of things is at least intelligible, whatever may be the diversity of opinions respecting its wisdom. Alderman Priestman says he is proud to have his name so prominently associated with the new enterprise, and we trust he will never have occasion to think differently. People who lay foundation-stones are allowed to be enthusiastic; but the man who knocks the building down in the fulness of time is in a better position to judge of its utility. Meanwhile, it appears from the Alderman's admissions and apologies that local opinion accuses the electric lighting works of hanging fire in some way. It is a long time since the Gas Committee were authorized to carry out the scheme; and there is as yet very little to show the public. The Bradford people are now promised that the works shall be ready for a start early next year; and the Chairman of the Gas Committee assures them that the light, when they get it, will be immensely superior to the Corporation gas. A remark like this reads strangely as coming from such a quarter; but Alderman Priestman has been Chairman and Vice-Chairman of the Corporation Gas Committee for ten years; and familiarity appears to have bred contempt in his case. He evidently does not belong to the race of those who agree to the counsel of the old saying, that "it is good to be off with the old love before you are on with the new." Fortunately, the aberrations of an Alderman are not likely to materially affect the fate of a large and prosperous gas undertaking.

The Deptford electric lighting station, which was briefly described by us last week as an outcome of the Grosvenor Gallery lighting experiment, is to be rivalled by the Metropolitan Electrical Supply Company, whose principal station is to be somewhere near Waterloo, on the Surrey side of the river, but whose only present installation is in Whitehall. It is expected that the rivalry of these undertakings will settle the question of alternating *versus* battery transformers, which now divides electricians; the Grosvenor Gallery interest being committed to the former, while the Whitehall speculators put their trust in accumulators. It is difficult to see, however, what can be expected to be proved by the Whitehall experiment, because it seems to be designed merely as a kind of domestic annexe to some great buildings of residential flats occupying the choice site between Whitehall and the Embankment. The supply of electricity for lighting is to be identified with the hot and cold water and passenger lift services, as well as with fire-prevention, and, possibly, boot-cleaning and dish-washing. No reliable economical data can be obtained from an installation of this character. It would be as feasible to attempt the estimation of the working power of a navy from observations of the strength put forth by a powdered Belgravian flunkey when carrying a five-o'clock tea-tray into his mistress's boudoir.

An estimate of the probable cost of a municipal electric light station for Montreal, drawn up by Mr. Badger pursuant to instructions received by him from the Light Committee of the City Council, may be of interest, as showing the expense of electric light plant and working the same in Canada. Supposing one arc lamp to be capable of displacing four gas-lamps in the streets, it is reckoned that to light the City thoroughly would require 650 arc and 500 incandescent lamps. The estimate of plant contemplates two generating stations, capable of supplying 600 arc lamps each, to be erected one at each end of the city, with a view to the reliability of the service. The works and plant for supplying 600 arc lamps with power to increase to 800 lamps if needed, are expected to cost, inclusive of everything, the capital sum of \$279,125, which is somewhere about £55,830. The working expenses of such an installation, calculated on the basis of 800 lamps, inclusive of all charges, interest on capital being reckoned at 4 per cent., are stated at \$87,091, or about £17,420 per annum, which works out to 29-8c. per lamp per night, or about £21 15s. per lamp per annum. This does not greatly differ from the cost of maintaining arc lamps for street lighting in this country.

AMERICAN WATER-WORKS.—According to some statistical reports on the water-works of the United States which have lately appeared in the *Engineering News*, there are in the New England States 287 of these undertakings, with 5291 miles of mains; the capital invested being \$84,993,000.

THE LIGHTING OF SOUTH AFRICAN TOWNS.—A Company under the title of the South African Lighting Association was registered last week, with a capital of £50,000, in £10 shares, "to supply gas, electric, or any other artificial light within Port Elizabeth and King William Town and elsewhere in South Africa, or any islands or countries near thereto." Among the first subscribers are the following well-known gentlemen connected with the gas industry:—Mr. J. Cloudsley, Mr. S. Cutler, Mr. D. Ford Goddard, and Mr. Corbet Woodall. The first Directors of the Association are to be Mr. D. Ford Goddard, Mr. J. Mansergh, and Mr. W. Woodall, M.P.

SIR WILLIAM SIEMENS.

READERS of the JOURNAL do not require to be introduced formally to the subject of Dr. William Pole's recently issued handsome volume;* or, for that matter, to the writer. As one of the Metropolitan Gas Referees, Dr. Pole is to a certain extent identified with the interest of gas lighting; and he has proved the reality of his sympathy with the industry by devoting his great literary powers in several instances to the treatment of gas engineering topics. In connection with his tenure of the position of Honorary Secretary of the Institution of Civil Engineers, Dr. Pole has been the biographer of several of the most distinguished members of that body, to whose professional labours the material progress of the nation and the world is so largely due. Sir William Fairbairn, Robert Stephenson, and I. K. Brunel are among the eminent engineers of whose posthumous renown Dr. Pole has, in a sense, taken charge; but neither he nor any other biographer of the leaders of modern science and industry can look to have a more striking subject for a personal memoir than the late Sir William, long known as Dr. C. W. Siemens. Of the many who made the great man's acquaintance in his later days, when he was at the apex of his fame, during the years immediately preceding his death full of honours and riches, there must have been few who did not sometimes reflect on the extraordinary features of such a career. Here was a German by birth, who, like Professor Max Müller, although in a different sphere, adopted England for his country, and rose to the highest eminence in his profession, notwithstanding the disadvantages that must attend the efforts of an alien in competition for the world's prizes with men of the race that has taught the rest of the peoples of the globe how to work. It seems natural for Englishmen to go out from their teeming native land, and take as a matter of course the high places of engineering in other countries; but by what means did a German conquer England so as to place himself at the head of the most English of professions? Such a conqueror must be a marvellous man, look at him in whatever light we choose. One must acknowledge that the true story of the life of such a man, however baldly told, provided that the facts are dependable, is bound to be interesting to all who find themselves in the same way of life, striving after the same kind of prizes, and encountering the same order of difficulties and hindrances. How much more then is such a biography likely to be instructive and interesting when written by an experienced and graceful author, instinct himself with sympathies both for his subject and for his readers? As an Englishman, an engineer, a man of science and of the world, as well as a man of imagination, Dr. Pole may be trusted to feel the quality and aim of that curiosity which Sir W. Siemens's career inspired in the more thoughtful of his countrymen, and consequently may be expected to understand in the proper spirit his duty as biographer. The inquiry that would rise to the lips of nine out of ten men who should be told anew of Sir W. Siemens's astonishing success in life, as success is popularly measured—how he came over from Germany a young man without any exterior advantages, and among an insular people reputed to entertain a prejudice against foreigners, rose to great honour and wealth, dying a Knight, with the awe-inspiring capitals F.R.S., D.C.L., LL.D., after his name, a special service in Westminster Abbey being held over his remains—the natural question, we say, that would arise in the mind of a hearer of such a tale would be, How was it done? What was there in the birth, training, position, or powers of the man that carried him all the long way from that solitary landing from the German packet to the last triumphant scene in the Abbey? It is a progress that would impress the most heedless who should stay for a moment to ponder over it. Let us see how Dr. Pole explains this great wonder, this romance of a prosaic age, this conquest of a time and with the forces of Peace.

The author, after briefly but most clearly and effectively giving his reader to understand that he is about to tell the story of an engineer, and explaining this last term in a very striking style, tells us that the Siemens family had been for three centuries country people, cultivators of the land, in a place called Wasserleben, on the northern edge of the Harz Mountains. The modern interest begins with Christian Ferdinand Siemens, born in 1789, the youngest son in a large family, who married early and settled as a farmer of Government land at Lenthe, near Hanover. All the family were well educated, thanks to the school and university system of the country. With the customary blindness to prudential considerations that often serves the good purpose of bringing out the resources of men and furthering the development of nations, the young couple Ferdinand (as he was usually called) and Eleonore Siemens had a large family of eleven sons and three daughters, of whom three sons and one daughter died in infancy. Knowing what we now do of the new industries that were to be created by more than one of these lads, giving employment in different parts of the world to tens of thousands of their fellow-men, it becomes a curious question for inquirers who admit the cogeny of the Malthusian principle of population, as to whether the Siemenses of Lenthe were not doing more good in giving William, Werner, Frederick, and Carl to the world than if they had consulted Malthus, and brought forth the prudential one or two offspring to carry on the family name. This, however, is a digression. Ferdinand Siemens was fairly prosperous as a farmer, but he could not do more for his numerous progeny than give them all a plain but substantial education. He

* "The Life of Sir William Siemens, F.R.S., &c." By William Pole, F.R.S. Illustrated. London: John Murray; 1888.

died in 1839, six months after his wife; and a few years later the family dispersed among their relations and friends. The exceptional quality of the new generation of Siemenses was first shown in Werner, the eldest son, who has been generally known as "the Berlin Siemens," and is deservedly honoured by Dr. Pole as the founder of the fortunes and reputation of the family. Born in 1816, Werner became a scientific soldier, distinguishing himself in the Prussian artillery service. He took up very warmly the new science of electricity, and became an authority upon telegraphy; founding with a friend the well-known house of Siemens and Halske, for the manufacture of electrical apparatus, while yet a military officer. The venture succeeded, and ultimately Werner quitted the army, and devoted himself to his own business. Honours have been showered thickly upon him, and he was ennobled by the Emperor Frederick III.; wherefore he bears the aristocratic prefix "*von*" to the family name. The brothers Siemens have worked so closely together throughout their lives, that it is impossible to tell the story of one without bringing in the others. This is especially true of William; because, although to the majority of Englishmen he seemed to stand for himself alone (none of the other brothers being visible in English business), he was really for the most part the representative of a fraternity in which Werner and Frederick, "the Dresden Siemens," were the great originators. The second son, Hans, is not heard of now, but he was a useful member of the brotherhood, for, having made money in distilling, he set up at Dresden the glass-works in which Frederick's regenerative furnaces were perfected. It is interesting to learn that the clever Frederick of later life ran away from school, and went for a sailor, working for two years before the mast. His good brother Werner, ten years his senior, and occupying the place of their dead father, tried to conform so far to the lad's taste as to get him into the Prussian navy; but while waiting for the appointment, which never came, Frederick took part in his brothers' electrical work, which interested him so deeply that he abandoned the sea, with the result that we know. The sixth son, Carl, is a good working member of the brotherhood—not much of an inventor, but an executive hand. The brothers Werner, William, Carl, and Frederick worked so well together that Dr. Pole admits the difficulty of exactly defining their personal shares in the many useful inventions and business enterprises for which the world is indebted to them. We may add to this remark of the biographer the observation—not at all intended to be understood in a depreciatory sense—that, from his figuring as the representative of the family in this country, William came in personally for a good deal of the honour and repute that was earned by the others, who were not merely in the background of absence from the country, but did not participate in his genius for publicity.

Dr. Pole's narrative of the childhood and youth of Sir William is highly interesting. As a boy he did not show any decided mechanical "twist;" and at first prepared for a commercial life. As in the case of so many other boys, his parents did not know what was to become of him, and it was by his brother Werner's desire that he was devoted to a mechanical career, studying at Magdeburg and at the University of Göttingen until he was 19 years of age, when he began to learn practical engineering and electricity. He corresponded regularly upon technical matters with Werner, who in all things supervised his educational course. Early in February, 1843, William started for London by way of Hamburg; his mission being to try to do some business in his and Werner's electric-gilding and galvanic battery inventions. He even then entertained the idea of settling in England, if he could see his way. His first business transaction in England was with Mr. Elkington, who was just then developing the electro-plating processes with which his name is historically united. It was from the Messrs. Elkington that the young German received his first lift in life, in the shape of a sum of £1600 for his patent. Strangely enough, Dr. Pole remarks that this process was not commercially used to any large extent. The biographer rightly lays stress upon the personal qualities of business tact and address that must have belonged to the young man of only 20 years of age who could negotiate a transaction of such importance in a foreign land, the language of which was strange to him. The ease with which this Elkington money had been earned stimulated the brothers to bring out other inventions, and William's success as a business agent stamped him out for the ambassador of the firm. Consequently, after a little more work in the Magdeburg machine factory, William started for London a second time, in charge of his brother's invention of a chronometrie governor, together with one or two other similar "notions," and associated himself with an English engineer, Mr. Joseph Woods, brother of Mr. Edward Woods, who was then practising in Westminster as a Civil Engineer. This device, though well spoken of by many eminent mechanical engineers of the day, does not appear to have been a permanent success. A printing process, likewise not successful, was also in hand at the same time; and the result of these failures was to plunge William, and through him the rest of the family, into money troubles. The Elkington success made them all too sanguine; and they undertook more than they could carry out, even if the schemes had been good for anything, which was unfortunately not the case. At this time it appears that the fortunes of the Siemens family were at a low ebb. Werner declined to have anything more to do with the governor and printing schemes, and renounced all benefit that might be derived from them by William in the future. The fraternal association was for the time broken. William had

realized and spent all his little patrimony in the attempt to make a success of these impracticable inventions. For two years and a half he worked at them fruitlessly; being often tempted to let them and the money sunk in them go, and to take a salaried situation. Although he could have secured his own livelihood in this way, he could not for a long time make up his mind to relinquish the prospect of getting back the money which his friends had entrusted to him to invest in his schemes. From this time for some years the history of the Siemens brothers is one of a succession of struggles. Messrs. Fox and Henderson paid William Siemens £400 a year for several years, and engaged to carry out some of his devices. But they lost a good deal of money by him; and the connection was ultimately severed. Werner Siemens and Halske meanwhile developed their electrical engineering business, which was a success from the first. This was the turning-point of their fortunes; for William was at last wholly engaged in representing the thriving firm in England, in which he was helped by Frederick. Werner's noble spirit is displayed in a letter offering this arrangement to the then unsuccessful brother, in which he says that William shall name his own share of the profits; "but do not make it too small," he urges, "for I would rather see five dollars in your pocket than two in my own."

The story of William's failure to make the principle of heat regeneration work in connection with steam-engines, leads up to Frederick Siemens's "happy idea," as Dr. Pole calls it, of the regenerative furnace. William pushed the discovery with his usual energy. Up to this time he had been very unfortunate with his own inventions; and Dr. Pole admits that the rotary water-meter was the first success that he achieved after he was settled in England. It is not concealed, however, that William Siemens did best as agent of, and afterwards as partner in, the firm of Siemens and Halske; the Charlton works being founded as a branch undertaking of the Berlin firm. The account of the introduction of the Siemens-Martin steel process is interesting; and the same may be said with emphasis of the story of the Siemens electric lighting inventions. There is very much in the biography which we cannot even allude to here. Suffice it to say that the writer has done his work well. He has given us a picture of the man, without indulging in too much laudation. He is sympathetic, but never fulsome, and does not conceal how much his subject owed to others. It is not his fault if one rises from the perusal of his book with a confirmed idea that, although William was in the end one of the most celebrated of the brothers Siemens, he was really neither the greatest nor the cleverest. The printing and general get-up of the book are all that can be desired. There are several illustrations; and the book is prefaced by a beautifully executed vignette portrait of the subject.

REDUCTION IN PRICE BY THE CHARTERED GAS COMPANY.—The Secretary and General Manager of The Gaslight and Coke Company (Mr. J. Orwell Phillips) informs us that the Directors have resolved, from and after the 1st of January next, to reduce the price of gas to private consumers on the north side of the Thames to 2s. 6d. per 1000 cubic feet for common, and to 3s. 1d. per 1000 cubic feet for canal gas. This will be a concession of 8d. per 1000 cubic feet in the former case, and 4d. in the latter.

PRESENTATION TO MR. W. STEPHENSON.—The *employés* at the Great Cambridge Street station of The Gaslight and Coke Company last Tuesday presented to Mr. W. Stephenson, who is vacating his position as Chief Clerk of the station, in consequence of his transference to the Company's offices in the Horseferry Road, a testimonial in token of their regard for him, and as a memento of his pleasant intercourse with them during his fifteen years' service. It consisted of an ebony and gold striking clock, and a dinner service for Mrs. Stephenson. The Engineer of the station (Mr. J. W. Randall) presented the gifts, accompanying them with a few kindly observations; and Mr. Stephenson acknowledged them in appropriate terms.

THE PARIS MUNICIPAL ELECTRIC LIGHTING STATIONS.—According to the Paris Correspondent of *Industries*, seven firms—viz., the Société Continentale Edison, the Société Lyonnaise, the Société Alsacienne, the Société d'Eclairage Electrique Jablochkoff, M. Patin (representative of Mr. Ferranti), M. Victor Popp (representative of the Thomson-Houston Company), and M. Crenod-Sautter—have tendered for the supply of the plant required for the electric lighting stations which the Paris Municipality are about to establish. The tenders were opened on the 26th ult., and handed over to a Sub-Committee, under the presidency of M. Mascart, who will examine the merits of the rival schemes, and recommend one for adoption. The decision is expected to be given in about six weeks.

THE GAS INSTITUTE TRANSACTIONS FOR 1888.—The volume of Transactions of The Gas Institute for the present year was issued to the members last week by the Secretary (Mr. W. H. Bennett), under whose editorship the book has been produced. Beyond the papers read at the meeting of the Institute in June, with the discussions thereon, it contains, in an Appendix, the communications presented by Dr. Wm. Wallace and Mr. Geo. Livesey—on "The Effect of Temperature on the Quality of Gas produced in Gas-Works at different Seasons of the Year," and on "Commissions"—which there was not time to lay before the members. The other matter consists of the report of the proceedings at the meeting of the donors and subscribers to the Benevolent Fund, the usual lists of office-bearers and members, the rules, and the statements of the financial position of the Institute.

Notes.

"WATER OIL GAS" FOR STEEL MAKING.

What is called in the newspaper reports "water oil gas" is in course of trial as a fuel for use in the conversion of steel at the Barrow Steel-Works, Barrow-in-Furness. The oil used is commercial creosote, not treated in any way for purification. From the creosote tank the oil is pumped to the furnaces, where it is passed through tubes kept hot by the flame of a portion of the gas produced. The gas thus made is mixed with superheated steam, which is stated to be prepared by passing steam at the initial pressure of 80 lbs. to the square inch through copper pipe heated to about 2000° Fahr. After the combination of the steam with the gas, the mixture is led to steel-furnaces, which were previously heated by Siemens producer gas. The combustion in the furnaces is described as perfect, and the heat obtained as most intense. The supplies of oil and steam are under the control of one man. An important claim made by the patentee is that, by the use of his so-called "water oil gas," a portion of the sulphur is eliminated from the steel. The process is described as being very convenient and clean, and not expensive in application. The cost of the creosote is stated as 1½d. per gallon; and from 25 to 30 gallons will produce a ton of finished steel. The process is said to be preferable for many reasons to the Siemens gas-heating arrangement previously employed; but no satisfactory evidence in support of this claim is offered.

THE FUEL VALUE OF WEATHERED COKE.

The American *Age of Steel* discusses briefly the question whether coke is injured for foundry purposes by long exposure to weather; stating that a wholesale coke merchant has contended that coke is really improved by this treatment. It is remarked, in support of this observation, that about 375,000 bushels of coke were supplied to a blast-furnace, but not used for four or five years, during which time the fuel was stored in a damp place close to a river. Finally, a neighbouring steel-works, being in straits for fuel, sent for this old stock as a last resource; and, to the surprise of everybody concerned, more and better iron was made by its means than had been customary with fresh fuel. At a small stove foundry also, a strike of coal operatives compelled the manager to dig up a few waggon-loads of coke that had lain neglected for several years in a damp cellar, subjected to the action of dripping water. This dirty-looking stuff gave splendid results in the cupola. From this, while it is not inferred that it is economical to allow coke to crumble and weather for years, it by no means follows that what remains after such neglectful treatment is worthless.

THE COMPOSITION OF COAL DUST.

At a recent meeting of the North of England Institute of Mining and Mechanical Engineers, Professor P. P. Bedson, D. Sc., of the Durham College of Science, contributed to our knowledge of coal dust by reading a paper dealing with the composition of this material. He stated that some time ago a member of the Institute drew his attention to the remarkable behaviour of a particular class of coal dust at one of the collieries under his superintendence, and suggested that it would be desirable to ascertain whether it contained gases, like coal itself. The author stated that the investigations of Herr von Meyer in Germany and of Mr. W. J. Thomas in this country, have demonstrated that coal holds varying quantities of gases enclosed in it—the gases consisting mainly of mixtures of carbon dioxide, nitrogen, oxygen, and marsh gas (CH₄). The gases enclosed in the coal were obtained by placing it in suitable vessels and exhausting them by a Sprengel pump, and at the same time heating the coal at 100°C. (212° Fahr.); drawing off the released gases by the continual flow of mercury. An account was then given by the author of the results obtained by submitting to a similar process coal dust collected fresh from the screens. The dust was found to contain, like coal itself, gas occluded in it, and in considerable volume. The analyses of these gases indicated a general resemblance in composition to those obtained by Herr von Meyer, and further that the combustible portion of the gases consisted in all probability in part of hydrocarbons related to olefiant gas (C₂H₄) and of members of the series to which marsh gas belongs, similar to those forming the natural gas issuing from petroleum wells. The author thought that, as a coal dust from one source only had been examined, it would be premature to draw any general conclusions from the results obtained; and it is his intention to submit coal dusts and coals from different sources to similar examination. Should further investigations confirm the results obtained, the existence of gases enclosed in coal dust, together with the nature of the combustible portions of these gases, will, it is thought, aid in some measure to explain the influence of coal dust in colliery explosions.

THE WROUGHT-IRON PIPE INDUSTRY IN AMERICA.—There are 24 wrought-iron pipe works in the United States—1 in Massachusetts, 2 in New York, 14 in Pennsylvania, 1 in Delaware, 1 in West Virginia, 2 in Ohio, and 3 in Illinois. Of the 14 in Pennsylvania, 6 are in Pittsburgh. All the others are in the eastern part of the State; 4 being in Philadelphia. The growth of this industry has been remarkable during recent years; and it now consumes a substantial proportion of iron produced. This kind of pipe is used in America for purposes not dreamed of a few years ago; and the promise is that it will occupy a still wider field. Originally made

for conveying water, steam, gas, oil, &c., it is now also employed in the construction of cars, for railing and fencing, and in numerous other ways.

A NEW CREOSOTE LAMP.—There has recently been introduced a new lamp which will compete with those already in use for the burning under pressure of inferior oils. The principle of the apparatus is that compressed air is used to effect the combustion of the oil only for a short time after the lamp is lighted. A coil placed over the flame serves to generate steam wherewith the pressure is supplied. The lamp is thus, excepting at the commencement of operations, self-acting.

A LARGE IRON RESERVOIR.—The largest iron reservoir ever constructed in America is that for Malden, Massachusetts. The city has made a contract with the Cunningham Iron-Works Company, of Boston, for the sum of \$20,940, to build a wrought-iron reservoir to contain 1,158,000 gallons of water. It will be 75 feet in diameter and 35 feet high, and be formed of plate iron ¾-inch in thickness, and a tensile strain of 50,000 lbs. per square inch of section. The weight of water when the reservoir is full will be about 4344 tons.

THE DINSMORE GAS PROCESS.—We are asked to state that the illustrated description of the Dinsmore gas apparatus which appeared in our "Register of Patents" last week (p. 764) does not show the final arrangement of the plant as now in operation at the Widnes Gas-Works. The design contained in patent No. 15,852, of which we gave an abstract, was only an experimental one; and the Dinsmore Company have, we understand, since developed the invention, and taken out further patents (which will shortly be published) to make it suitable for gas manufacturing purposes.

PROPOSED ELECTRIC LIGHTING OF THE MANSION HOUSE.—At the meeting of the Court of Common Council last Thursday, Mr. J. Judd moved to refer to the General Purposes Committee the consideration of the best means of lighting the Mansion House by the electric light, with power to obtain tenders and estimates for the necessary works, and to submit them to the Court. For the purpose of their inquiry, the Committee were to be authorized to expend a sum "not exceeding twenty guineas." This was approved, after a protest from Mr. Morton, that the expenditure was "useless and wasteful."

AMERICAN GASLIGHT ASSOCIATION.—Mr. George Shepard Page, who, it will probably be remembered, was on a visit to this country at the time of the last meeting of The Gas Institute, as representative of American associations of gas managers, has sent us, under date of the 24th ult., the following brief notice of the recent meeting of the above-named Association, reference to which was made in our columns last week:—"The sixteenth annual meeting of the American Gaslight Association has just concluded its session at Toronto, Canada. During nearly all the years since its organization, we have been largely aided in our deliberations by the contributions of our friends on the other side of the border—Mr. H. W. Pearson, Secretary and General Manager of the Consumers' Gas Company of Toronto; Mr. F. W. Gates, President, and Mr. T. Littlehales, General Manager, of the Hamilton (Ontario) Gas Company; Mr. R. Baxter, General Manager of the Halifax Gas Company; Mr. J. F. Scriver, Manager of the Montreal Gas Company; and D. H. Geggie, Manager of the Quebec Company. It was therefore high time that the Americans crossed the border. It would be impossible to say too much in praise of the efficient management by the Committee of Arrangements, or of the great hospitality of the Consumers' Gas Company and the citizens of Toronto. Great surprise was expressed by many Americans who had never before visited Toronto at the extent, prosperity, and enterprise of this great city. Its public buildings and private residences would do credit to any metropolis of the Old or the New World. But the greatest astonishment was experienced during the inspection of the magnificent new works of the Consumers' Gas Company, now nearly completed. They will not be surpassed in any country. A splendid banquet was tendered to the members of the Association by the Consumers' Gas Company. The menu card that was prepared for the occasion contained some amusing and unique designs, the work of a young native Canadian artist. Regret was expressed that the meeting had not been honoured by the presence of a delegation from The Gas Institute. The following officers were elected for the ensuing year:—President—Mr. A. B. Slater, Treasurer and General Manager of the Providence (R.I.) Gaslight Company. Vice-Presidents—Mr. Emerson M. Millin, Vice-President and Engineer of the Columbus (Ohio) Gas Company; Mr. J. P. Harbison, Treasurer and General Manager of the Hartford (Conn.) Gas Company; and Mr. W. H. White, Gas Engineer, of New York. Members of Council—Mr. W. H. Pearson, Secretary and General Manager of the Consumers' Gas Company of Toronto (Canada); Mr. T. Turner, President and Engineer of the Charleston (S.C.) Gas Company; Mr. G. G. Ramsdell, Treasurer and Manager of the Vincennes (Ind.) Gas Company; Mr. A. B. Boardman, General Manager of the Macon (Georgia) Gas Company; Mr. W. Cartwright, Engineer of the Oswego (N.Y.) Gas Company; Mr. C. W. Blodget, Secretary of the Williamsburgh (N.Y.) Gas Company; and Mr. R. E. Chollar, Manager of the Topeka (Kansas) Gas Company. Secretary and Treasurer—Mr. C. J. R. Humphreys, General Manager of the Lawrence (Mass.) Gas Company. The next annual meeting is to be held at Baltimore (Maryland), in October, 1889. A large number of new members were elected."

Technical Record.

MIDLAND ASSOCIATION OF GAS MANAGERS.

The Thirty-third Quarterly Meeting of this Association was held, on Thursday, the 18th ult., at the Grand Hotel, Birmingham. The PRESIDENT (Mr. Henry Hack, M. Inst. C.E., Engineer of the Saltley works of the Birmingham Corporation) occupied the chair, and there was a good attendance of members and friends.

The HON. SECRETARY (Mr. W. R. Cooper, of Banbury) read the minutes of the previous meeting, and they were confirmed.

ELECTION OF NEW MEMBERS.

The PRESIDENT proposed the election of the following gentlemen as members of the Association:—Mr. E. H. Millard, of Hinckley; Mr. J. C. Belton, of Wellington, Salop; and Mr. W. W. Hulse, of Longton.

Mr. TAPLAY seconded the motion, which was carried.

THE PROPOSED LECTURES ON GAS MANUFACTURE.

The PRESIDENT: Gentlemen—You will remember that at the last meeting in Birmingham, a Committee was appointed with reference to the matter of lectures on gas manufacture. They have since had the subject under consideration, and have seen Dr. Tilden, of Mason's College, and discussed the idea fully with him. He kindly stated that he believed the Governors of Mason's College would be willing to further the object as much as was in their power; and, subject to the approval of the members of the Association, he himself would in January next undertake to give a course of lectures upon the chemistry relating to gas manufacture. The Committee recommended that this offer be accepted. They believe the funds at their disposal will cover the cost of the lectures. I therefore beg to move—"That the recommendation of the Committee be approved, and that they be authorized to arrange terms and all other matters with Dr. Tilden."

Mr. W. NORTH (Stourbridge): In order that the matter may be discussed, I will second the motion.

Mr. H. TAPLAY (Stoke-on-Trent): In rising to move an amendment, I would remind the meeting that, when this subject was first discussed, it was decided that a professional man should be employed to give instruction to the members of the Association. This was slightly modified sometime afterwards, on the proposition of a member of the Council of The Gas Institute, that the funds to be employed for the purpose be thrown into the general funds of The Gas Institute. [A VOICE: No; not "thrown into the funds."] Well, the money was virtually to be voted for The Gas Institute.

The PRESIDENT: Voted for gas lectures.

Mr. C. HUNT (Birmingham): In conjunction with The Gas Institute, to be expended in this locality.

Mr. TAPLAY: As The Gas Institute will probably undergo serious revision, I desire to propose that the matter be left open for the present, and that the money for the lectures be not voted at this meeting. When the Institute is revised, and matters put straight, we may consider the whole matter again.

The PRESIDENT: I am bound to point out that the money has already been voted. You can propose that the matter be deferred, but not that it will be rescinded, without giving notice.

Mr. TAPLAY: I do not want to rescind it at the present time; but I simply wish the consideration of the expenditure of the money to be deferred.

Mr. V. HUGHES (Tipton): Is the money being expended in connection with The Gas Institute.

The PRESIDENT: It is not intended to be expended in connection with The Gas Institute.

Mr. HUGHES: Then it is not being spent in accordance with the resolution.

The PRESIDENT: It is not being expended at all at present.

Mr. HUGHES: To my mind, the resolution does not want rescinding, because it is a new scheme that is suggested by the Committee; and we may either accept or reject it.

The PRESIDENT: It is only carrying out the idea approved at a previous meeting. The lectures were to be entrusted to a local Committee; and this Committee has been formed by you.

Mr. HUGHES: And the funds of The Gas Institute were to assist us; but we are getting none.

The PRESIDENT: Not at present.

Mr. HUGHES: What I want is information on the subject. First it was proposed to have special lectures for ourselves; and then we had a scheme which was to be in connection with The Gas Institute. But now we have another proposal without The Gas Institute.

Mr. HUNT: I am sure that what the President intended to explain was that the first thing this meeting has to determine is whether we shall go on with the scheme in the present unsettled state of affairs with respect to The Gas Institute. Your Committee deliberated upon this point; and having regard to the fact that they were able to place before you a scheme on all fours with that which would in all probability have been adopted in conjunction with the Institute, and at a cost not exceeding the sum voted by the Association, they felt it to be their duty to put the matter in your hands. We have, however, no feeling at all on the subject. If you adopt the resolution, you will be doing precisely the work which was intended in conjunction with The Gas Institute; but it is for you to say whether we shall go forward alone, or postpone action for, perhaps, an indefinite time.

Mr. B. W. SMITH (Smethwick): The reason of this matter being

introduced to-day was that, in view of the unsettled condition of The Gas Institute at present, the Lecture Committee did not think it wise to defer it for another year. Hence they thought it better to bring forward some proposition for the meeting to discuss.

Mr. W. WINSTANLEY (Newcastle): Is it proposed that the lectures shall be in Birmingham only, seeing that some of the members come from Derby, North Staffordshire, Shrewsbury, and other places at a distance?

The PRESIDENT: The present recommendation is that the first course shall take place at Mason's College.

Mr. WINSTANLEY: Then I will second the amendment, as I think the lectures should be arranged to be given in different centres, so as to meet the requirements of members living at long distances from Birmingham, and who could not possibly attend if they are to be restricted to Birmingham only.

Mr. P. SIMPSON (Rugby): When the question of our balance was referred to, it was thought it would be a good thing to have an experienced man to give lectures to the Association; but when The Gas Institute took the question of technical education in hand, and proposed that courses of lectures should be given in different parts of the country, we thought it better to wait and see what they would do. As, however, things have taken the course they have, I do not think we should ignore the wishes of our members by passing the matter over. We considered it our duty to recommend that a lecture or lectures be given; and it was considered that we were only carrying out what was your wish, before the Institute recommended their proposal. We have no desire to work against the Institute. Considering the offer we had from so experienced an authority as Dr. Tilden, the Committee thought if they could arrange for a course of lectures in Birmingham, which is our centre, they would be meeting the wishes of the members.

Mr. TAPLAY: That may have been understood by the Committee, but not by the members. In my opinion, and that of members I have spoken to, with the assistance of The Gas Institute, we should have a lecturer for the members of the Midland Association. Well, now, the proposed lectures are not confined to the members of the Midland Association, but are to be open to students; and every one connected with gas-works could come in by paying a small fee. I did not look at the matter in that light, and did not understand it in that way at first. I thought it was proposed to have a series of lectures throughout the country, in centres where men in years could go and learn something. I take it that, as members of this Association, we do not want elementary lectures. If you have a lecturer who gives advanced views to a lad of sixteen, what good would that be to me? We want a man from whom we can learn something ourselves. Speaking personally, I am a little bit disappointed. I have no doubt the Lecture Committee have very fully weighed the matter; but I do not see what advantage the whole of the Association would get out of it. You take the Association's funds, and pay them to a lecturer for somebody else; and it may be made a whip for our own backs. I confine myself now to moving an amendment to defer the matter, and if necessary I will give notice that the resolution be rescinded at the next meeting.

Mr. HUNT: Allow me to correct Mr. Taplay. It was not intended by the resolution adopted at the meeting of The Gas Institute last time to provide lectures for members only. Members were to have the privilege of attending the lectures free; but it was not contemplated to exclude others, who were to be admitted on payment of a fee. In the proposal before the meeting, we should not be departing in the slightest from the original proposition submitted to The Gas Institute and discussed at the June meeting. It is on precisely the same lines as then laid down, and upon which the Institute Committee would now have been at work had they continued in existence.

Mr. TAPLAY: I accept Mr. Hunt's explanation; but the matter was not in the minds of the members generally in that shape.

The PRESIDENT: I admit that, at the last meeting in Birmingham there was at first some little doubt as to what was intended; but after the explanations given, I take it the members knew perfectly well what was proposed. Mr. Taplay has been speaking of the benefits of a lecturer for ourselves as compared with The Gas Institute scheme. They are, of course, two quite distinct things. I may say that it is proposed to have six lectures for a course; and no doubt one of them can be made to coincide with the date of the February meeting of the Association.

The amendment was then put and carried by ten votes to seven.

DISCUSSION ON MR. LEWIS'S PAPER.

The discussion on Mr. Lewis's paper—on "The Competition of Petroleum with Gas for Lighting Purposes"—deferred from the previous meeting at Bath, was next taken; and it will be reported in the forthcoming issue of the JOURNAL.

AN OFT-REPEATED QUESTION: ARE HIGH CARBONIZING TEMPERATURES CONVENIENT AND PROFITABLE?

Mr. C. TAYLOR (of Derby) then read the paper, bearing the above title, which was given in the JOURNAL for the 23rd ult. (p. 719).

The PRESIDENT: I am sure we are all indebted to Mr. Taylor for bringing this subject before us; and if we are able to agree with many of the things mentioned in the paper he has kindly read, we shall all, I think, disagree with the concluding remark "that the subject is probably wanting in interest." In my opinion it is one of the greatest interest that can be brought forward, to all engaged in gas manufacture; and I should think it will lead to an animated discussion. There may be a difference of opinion as to what really constitutes high heats and low heats. Mr. Taylor seems to define them as the difference between producing 9000 and 10,000 cubic

feet, presumably from the same coal. Upon this point the members may perhaps contribute their opinion during the discussion which I now invite.

Mr. W. NORTH (Stourbridge): The paper opens up such a wide subject, that I think it would be better if we could defer the discussion. The whole question of regenerative furnaces will come in; and with such a large subject, I should be sorry to see it disposed of in the short time still at our command.

Other members having expressed the same view, as there was some further business on the *agenda*, it was agreed to postpone the discussion.

THE REPORTS OF DISTRICT GAS ASSOCIATIONS.

Mr. C. MEIKLEJOHN (Oldbury) moved—"That the reports of District Associations be no longer supplied gratuitously from the funds of this Association." His notice of motion, he said, arose from the decision to devote £10 towards establishing a centre for gas lectures, and because this would entail a deficit of about the sum granted for these reports. He gave notice of the motion as it was very unwise to propose expenditure exceeding their income; and, secondly, because he considered the £10 could be expended in a much better way. He questioned if more than one-tenth of the members read the papers, except as they appeared from time to time in the *JOURNAL*.

The PRESIDENT said it was not intended to present the District Association reports to the members again, unless the Committee brought forward a recommendation to that effect.

Mr. HUNT stated that, owing to the unsettled state of The Gas Institute, the establishing of lecture centres had been postponed; so that the expenditure would not be incurred.

Mr. MEIKLEJOHN under the circumstances withdrew his motion.

ELECTION OF OFFICE BEARERS.

The PRESIDENT: The next business is the election of President for the ensuing year. I beg, on behalf of the Committee, to propose the election of Mr. Charles Taylor, of Derby, to this position for the ensuing year. We have known him a considerable time; and he has been a useful member on the Committee. He has been a valuable and tolerably regular attendant at our meetings, and has taken a fair part in our discussions. He is in every respect, I think, fully qualified for the honour the Committee recommend you to confer upon him.

Mr. CRANMER: I have pleasure in seconding the proposition.

The resolution was carried with applause.

Mr. TAYLOR: Mr. President and gentlemen,—In electing me to fill the office of President, I am sure I feel you have done me a very high honour. I am only afraid that, in following so able a President as Mr. Hack, I may fail to fulfil your expectations, and to administer the affairs of the Association as successfully as he has done. I thank you very sincerely and heartily for the honour you have done me.

Mr. SMITH proposed the re-election of Mr. P. Simpson, of Rugby, as Treasurer of the Association.

Mr. F. J. NORTH seconded the motion, which was unanimously agreed to.

Mr. SIMPSON said he was much obliged to the members for their continued confidence. They were getting very rich, and ought to have someone they could trust. (Laughter.) However, he would do his best, as they wished him to continue in office.

The PRESIDENT said he was sorry to announce that Mr. Cooper felt himself no longer able to carry on the duties of Secretary. He was exceedingly unwell in February last, and felt he could not go on to the end of the year; but with the offer of help made to him, he had consented to do so till the present annual election of officers took place.

Mr. W. NORTH proposed that Mr. J. S. Reeves, of Bilston, be elected to the office of Honorary Secretary.

Mr. J. WARD (Brierley Hill) seconded the motion, and it was carried unanimously.

The PRESIDENT observed that there were three members to elect to serve on the Committee, including one to take the place of the new Secretary. He moved the election of Mr. Cooper (Banbury), Mr. Littlewood (West Bromwich), and Mr. Bell (Stafford).

Mr. WINSTANLEY seconded the motion which was agreed to.

On the motion of the PRESIDENT, seconded by Mr. HARRIS, Mr. W. T. Tew, of Warwick, and Mr. J. T. Lewis, of Wellingborough, were elected Auditors.

VOTES OF CONDOLENCE.

Mr. W. NORTH: We have to mourn the loss of two members of the Association during the year—Mr. Collett, of Dudley, and Mr. J. H. Smith, of Sutton-in-Ashfield. It has been suggested that letters of condolence be sent to the friends of these deceased members; and I move that this be done.

Mr. SIMPSON seconded the proposition, which was unanimously carried.

VOTES OF THANKS TO THE PRESIDENT.

Mr. TAYLOR: I beg to move a vote of thanks to the retiring President for the services he has rendered to the Association during the past year, which is the second year of his presidency. I have a very high opinion of Mr. Hack, who has been as successful as he has been earnest in his efforts on behalf of the Association. I hope we shall, at no distant day, again see him in the position he has filled so well. I have great pleasure in proposing a very cordial vote of thanks to Mr. Hack.

Mr. H. WOODALL (London): I beg to second the resolution. It would be impossible to find a better man for the position he has held than Mr. Hack. He has all the qualifications which go to

make a chairman. His urbanity is known to all; and he is particularly fitted for office by his care in all matters coming before him. If I want exact information, I do not know where I could go for it better than to him.

The resolution was carried, with acclamation.

The PRESIDENT: Gentlemen,—I thank you most sincerely for the kind and hearty vote of thanks you have accorded me on the termination of my office to-day. When I entered on the post two years ago, I had great misgivings as to my fitness to occupy it; remembering the ability of those who had filled it before, and that some of them had also so ably occupied the similar, yet more important, position in The Gas Institute. In deference, however, to your kind wishes, I accepted the honour; and though I may not have come up to your expectations, I can conscientiously say that I have endeavoured to discharge the duties in a satisfactory manner. I hope that the kindness and support I have received from you at our meetings and at all times will be extended to my successor.

POSITION OF THE GAS INSTITUTE.

Mr. SIMPSON: I ask the President just to allow me a minute or two. I am glad to see representatives from the Council of The Gas Institute here; and as we are at present members of the Institute, I would ask if they would put something before us, before we pay another guinea, as to what steps are to be taken to rectify the existing state of things. Something should be done, or some may cease to be members before any vote is taken.

Mr. WOODALL: I am sure you will all sympathize with me in the position in which I am placed. It is simply a policy of reticence which is being pursued by myself and other members of the Council up to the present. But it is, I think, more than ever desirable that every member of the Institute should continue to pay his subscription and continue on the list of members. I can scarcely say more than that. The Council meet in November; and I have no doubt our policy will be put before the members then. I do not think it is desirable I should be drawn out to say more than this now.

THE RETIRING SECRETARY.

Mr. W. NORTH, in moving a vote of thanks to the retiring Secretary (Mr. Cooper), said that, with all respect to the gentleman elected, he wished they could have kept Mr. Cooper in office longer. They owed him their thanks for his services during the past two years; and knowing himself what the work was, he had much pleasure in proposing a vote of thanks to Mr. Cooper for what he had done.

The PRESIDENT seconded the motion; remarking that it would be a great omission not to give Mr. Cooper a hearty vote of thanks. Mr. Cooper had been a right hand to him during his own term of office; and he could fully understand the demands made before him.

The motion was carried, with applause.

Mr. COOPER heartily thanked the members for the kind vote they had passed in his favour. He said he took the office of Secretary because there was then a little difficulty about it; but he had had a most excellent President to work under, and he had perhaps sometimes taken the liberty of dictating as a kind father would. (Laughter.) They had all worked together most harmoniously; and his two years' service had been a pleasure to him. He declined the office again, not because he was afraid of work, but because of being overworked; and he explained that public work in Banbury as well as his professional work fully occupied him. Mr. Reeves would, he believed, find the same help and indulgence which he had received in holding the office.

This concluded the business of the meeting.

IMPROVED PUBLIC LIGHTING IN WHITECHAPEL.—Since the perpetration of the outrages at Whitechapel, to which reference was made in the *JOURNAL* for the 9th ult., the Works Committee of the District Board have had under consideration the necessity for improving the lighting of the district. At the last meeting of the Board, the Committee recommended a number of alterations in the arrangements of the lamps and burners at certain places where more light is urgently needed; and they were all agreed to.

ELECTRIC LIGHTING IN BERLIN AND VIENNA.—The correspondents of *Industries* in Berlin and Vienna give glowing accounts of the progress of electric lighting in these cities. The representative of our contemporary in the former city says that the work done by the Edison Company there is so good, that the public and the municipal authorities have perfect confidence in their ability to extend their central station work still further; and a concession has been given to the Company for the establishment of two new stations—one in the centre of the town and the other in the south-east quarter, where most of the engineering works and other factories are situated. Both stations must be ready within two years; and each must be able to supply current for 6000 glow lamps burning simultaneously. The station in the centre of the town will eventually be increased to a capacity of 24,000 lamps, and the other station will be increased to 12,000 lamps; the annual increase to be not less than 6000 and 8000 lamps respectively. In view of this extension of their business, the Edison Company propose to increase their share capital at present by £150,000, and later on by £300,000. In Vienna, all the public buildings will soon be lighted by electricity. For the contract for lighting the Houses of Parliament all the principal Austrian electric lighting engineers tendered. The order has been obtained by Messrs. Siemens and Halske. The new Town Hall is also to be lighted electrically by the 2nd prox.—the day of the Emperor's Jubilee.

GASEOUS FUEL.

By J. EMERSON DOWSON, M. Inst. C.E., &c.

[A Paper read before the British Association at Bath, Sept. 8, 1888.*]

At the York meeting of the Association in 1881,† I had the privilege of explaining for the first time, an apparatus with which I had succeeded in making a cheap fuel gas; and I gave the economical results of working some gas-engines with it. Since then I have gained a much wider experience in connection with this subject; my apparatus has been considerably improved; and the gas made in it has been much used, not only for driving engines, but for heating in many industrial processes. I propose, therefore, to give a short account of the development which has taken place, and of some of the more important results obtained.

Like other generator gas, mine is made by passing steam and air through incandescent fuel; and gas so made can be taken direct from the generator and burnt in a furnace without being purified or cooled. For such work large flames are used; and it is comparatively easy to deal with them. When, however, the gas is required for a gas-engine or for small burners, the conditions are very different. The gas must be clean, or troublesome deposits will occur in the pipes and cocks; and it must pass through a gasholder to ensure uniformity of pressure in the distributing pipes. It must also be cool; and this is especially the case for gas-engines, as, within certain limits, the cooler and denser the gas, the greater is the energy in the limited volume which can enter the cylinder. It is also essential that when small jets of gas are used, as in small burners, the gas should be fairly strong and of uniform quality, or the flames will not burn steadily. To anyone accustomed to the manufacture of ordinary lighting gas, these remarks, may, perhaps, seem too elementary; but it should be remembered that generator gas is usually required in considerable quantity, and that, to avoid large gasholders, it should be made as quickly as it can be consumed. In one case I have had to provide plant to make gas at the rate of a million cubic feet per day, or about 90,000 cubic feet per working hour; and, without extensive appliances, the cooling and cleaning of so large a volume of gas is not so simple as it may at first sight appear.

The original invention dealt with the generator only; but I have since found it necessary to devise a complete set of gas plant, to meet the requirements of practical work. In nearly all cases it is important that the apparatus should occupy as little room as possible; and the accompanying illustrations show the arrangement usually adopted. The steam-boiler is small, and specially made with a superheating coil, so that dry steam enters the generator. The gas from the generator passes through water in the washer, and then through a scrubber containing coke moistened by water. The scrubber is placed inside the gasholder tank, so as to occupy as little space as possible. The rise and fall of the gasholder is made to regulate the supply of steam to the injector; so that to a certain extent the production of gas can be regulated automatically to suit a varying rate of consumption. In some special cases the gas is passed through oxide of iron, to remove all traces of sulphuretted hydrogen; but for general purposes chemical purification is not necessary. The whole is very compact; and a plant large enough to drive an engine of 50 indicated horse power occupies a ground space of only 9 feet by 10 feet. I have always taken the view, and it has been confirmed by practice in many places, that when the consumption of gas is regular there is no need for a large

holder, provided the generator is well able to make gas at the maximum rate of consumption. In the case of engines, for instance, the gas plant is to the gas-engine what the boiler is to the steam-engine; and it is no more necessary to have a large reserve of gas than to have a large reserve of steam.

As regards the composition of the gas, it necessarily depends somewhat on the quality of the coal used, and on the fuel column being kept deep enough to ensure a reduction of the carbonic acid. It has been analyzed independently by Professor W. Foster and others; and, roundly speaking, the gas now made has the same composition as that made some years ago. I then thought that possibly in a large generator, containing a great mass of fuel at a high temperature, the percentage of hydrogen might be increased and that of the carbonic acid reduced. Trials since made have, however, shown that the average composition is much the same, whether the gas be made at the rate of 1000 cubic feet per hour in a small generator, or at the rate of 15,000 cubic feet per hour in a large one. In 1881 I stated that for gas-engines it was then necessary to use 5 volumes of the generator gas for 1 volume of ordinary lighting gas, to develop the same power. Theoretically, the comparative explosive force of the two gases is as 3·8 : 1; and it was evident that so long as practice required 5 to 1, the weaker gas was not being used to the best advantage. Since then some important modifications have been made in the "Otto" gas-engines; and I am glad to say that it is now necessary to use only four volumes of the generator gas. On this point, therefore, theory and practice are now fairly in accord. By calculation, the calorific power of 100 litres (3·53 cubic feet) of an average sample of the generator gas is 143,213 units of heat; while that of 100 litres of ordinary 16-candle power lighting gas is 569,264 units. Tests made with a calorimeter and in other ways confirm these figures approximately.

In 1881, only one engine of 3½-horse power had been worked with this gas; and this showed a consumption of 1·46 lbs. of coal converted into gas per indicated horse power per hour. Since then a large number of engines have been worked with it—one indicating over 80-horse power; and many independent tests have been made. Details of these will be found in a paper of mine contained in the Proceedings of the Institution of Civil Engineers for last year; * and on the present occasion it will be sufficient to give a few instances only. For more than four years Messrs. Crossley Bros., the English makers of the "Otto" engines, have used this gas exclusively at their works for an average of about 150-horse power; and, after a careful trial extending over 35 weeks, they found that the fuel consumption averaged only 1·3 lbs. per indicated horse power per hour, including all waste and the coal burnt in the generator every night and during Sunday (112 hours per week), when the fire was alight although there was no work. At the time of this trial, the construction of the generator rendered it necessary to draw the fire every two or three weeks to remove the clinkers adhering to the fire-brick lining. Since then I have altered the generator, so that when the fire has once been lighted, it need never be drawn. One of these generators has now been running continuously for upwards of a year; and Messrs. Crossley estimate that this saves about 20 tons of coal per annum. It is also worthy of note that at these large works, owing to the use of gas, there is no chimney except for the blacksmith's shop. The returns sent me by eleven users of "Otto" engines working regularly in different places, and each averaging 35-horse power,

also show an average fuel consumption of about 1·3 lbs. per indicated horse power per hour. Messrs. Ibotson, of the Colnbrook Paper-Mills, were supplied with a single-cylinder "Otto" engine to indicate about 45-horse power with this gas, on the guaranteed condition that the engine and gas plant could be worked continuously day and night, and that the fuel consumption should not exceed 1½ lbs. per indicated horse power per hour. A trial was made extending over two weeks—the engine being indicated day and night at frequent intervals; and the result showed that the guarantee was, in all respects, fulfilled. The "Otto" engine makers in Germany have made exhaustive trials with this gas in connection with several of their engines, and have fully confirmed the results obtained by Messrs. Crossley in this country. Professor K. Teichmann, of the Royal Technical School of Stuttgart, and Mr. F. Böcking, Chief Engineer of the Rhenish Society for examining steam-boilers, made a joint test of a twin-cylinder "Otto" engine worked with this gas. The engine developed a brake power of about 52-horse power; and the total fuel consumption, including that used for the superheating boiler, was 1·6 lbs. per brake, or barely 1·3 lbs. per indicated horse power per hour. Professor Witz, of Lille, a well-known scientific authority on the gas-engine, has tested two Delamare-Debouteville engines worked with this gas—one of 9-horse power, and the other of 25 effective horse power. The first trial gave a consumption of 89 cubic feet of gas, equal to 1·33 lbs. of coal per brake horse power per hour. I have not exact particulars of the second trial; but I understand from the maker of the engine (Mr. Thomas Powell, of Rouen) that the result was even more favourable. Seeing that all these results have been obtained under practical working conditions, the record is certainly satisfactory; and I am pleased to add that I have also many letters testifying to the ease with which the gas plant can be managed. This is an important point; for if the saving of fuel could only be effected in a complicated way, the apparatus could not be generally adopted. The total number of engines already made to work with this gas is 71; and the aggregate horse power is 2390, or an average of nearly 34-horse power each.

I consider myself justified in saying that gas power is now fairly launched in competition with steam power; and, to my mind, there are reasonable grounds for supposing that eventually the former will, to a great extent, supersede the latter. In this view I am confirmed by the late Professor Fleeming Jenkin, who, in his lecture at the Institution of Civil Engineers on "Gas and Caloric Engines," remarked: "Since theory shows that it is possible to increase the efficiency of the actual gas-engine two or even three-fold, then the conclusion seems irresistible that gas-engines will ultimately supplant steam-engines. The steam-engine has been improved nearly as far as possible; but the internal-combustion gas-engine can, undoubtedly, be greatly improved, and must command a brilliant future." It has been proved that the absolute efficiency of the gas-engine—i.e., the ratio between the indicated horse power and the total quantity of heat generated by the fuel per minute—is already about double that of the best steam-engine. As regards the mechanical efficiency—i.e. the difference between the gross indicated power developed in the cylinder and the effective power given off on the brake—in the condensing steam-engine it is taken at about 80 per cent., and in the non-condensing engine at about 85 per cent. In the gas-engine, I showed, in my paper at the Institution of Civil Engineers before referred to, that the average of several samples given was about 84 per cent. The "Otto" and other compression engines are of comparatively recent invention; and it is fair to assume that further improvements will yet be made, as the principles on which they should be based are now well understood. An important modification, for instance, has only recently been made in the "Otto" engine—the slide-valves being entirely dispensed with.

We have seen that the results already obtained with this generator gas are good; but I cannot help feeling that still better ones can and will be obtained when the engine is really designed to give the best effect with a gas of this kind. It is well known that in the "Otto" engines each new charge of gas is diluted with a portion of the products of combustion from the previous charge; and, for reasons I need not discuss, this answers very well with ordinary lighting gas. But, as generator gas such as mine has only about one-fourth the explosive power of the other gas, it is a disadvantage to dilute it with products of combustion. Sooner or later this point will, no doubt, receive due attention, especially as the economical use of gas-engines of high power must depend on their being worked with cheap gas. Looking to the probable extension of gas power, it is, in fact, most important that the best possible engine should be made for the fuel gas.

For gas-engines as now made, it is important that the generator gas should be as clean and free from sulphur compounds and ammonia as ordinary lighting gas. With this in view, the best fuel to use is anthracite, as it does not yield tar or other condensable products, which foul the pipes and valves. It is also suitable because it does not cake, and because it makes a dense fire free from holes. Good qualities of anthracite yield but a small percentage of clinker and of sulphur compounds, and no ammonia. With some special precautions, ordinary gas coke can also be used. The quality of gas coke varies, however, very much in different localities; and this is doubtless due, in some measure, to the different kinds of coal from which the coke is made, but also to the varying heats to which it is subjected in the retorts of different gas-works. Some coke yields very large quantities of clinker, and is quite unfit for use in such an apparatus as mine. Other samples yield less clinker; but, owing to the comparatively

low temperature to which they have been subjected in the retorts, they retain hydrocarbonaceous bodies, which vaporize in the generator, and are afterwards troublesome to remove from the gas. As before mentioned, these difficulties are not met with when the hot generator gas can be taken direct to a furnace; but when it is necessary to cool and clean the gas (as for engine work), special precautions must be taken.

Several trials have shown that when the gas apparatus is worked with anthracite, the actual fuel consumption is about 13 lbs. per 1000 cubic feet, including that used for producing the steam required; but, to cover all sources of waste, as well as inferiority of quality, I usually allow 15 lbs. per 1000 cubic feet passed into the holder under ordinary conditions of temperature and pressure. On this basis the yield of gas is a little over 149,000 cubic feet, or, allowing for the presence of 50 per cent. of nitrogen and carbonic acid, say 74,500 cubic feet of combustible gas per ton of fuel consumed.

To determine the working cost of a gas-engine driven with this generator gas compared with a steam-engine and boiler, the more simple and direct way is to take in each case the weight of fuel used per horse power per hour, as it is no more necessary to determine the volume of gas consumed than it is to know the volume of steam used. We have already seen that with this gas the fuel consumption of several "Otto" engines doing practical work in different places averages only 1½ lbs. per indicated horse power per hour. The wages of the attendant, the cost of repairs, and the other working expenses, are about the same as with a steam-engine of equal power. The great difference is in the consumption of fuel; and, to make an exact comparison, I have taken the returns last published by the Manchester Steam Users' Association for all engines indicating under 100-horse power for which the net fuel consumption is given. The details of these returns will be found in Appendix II. of my paper read before the Institution of Civil Engineers; and from these it appears that the average fuel consumption is 7 lbs. per indicated horse power per hour. If, however, an average be taken of five engines, each indicating 20-horse power, the fuel consumption will be over 11 lbs. per indicated horse power per hour. It is instructive, too, to note what Sir Frederick Bramwell said on the fuel consumption of steam-engines in actual work, in his address (January, 1885) as President of the Institution of Civil Engineers. He said: "In an investigation instituted last year by the Corporation of Birmingham, when considering whether they should approve of a proposal to lay down power-distributing mains throughout their streets, it was found on indicating some six non-condensing steam-engines taken indiscriminately from among users of power, and ranging from 5 up to 30 nominal horse power, that the consumption in one instance was as high as 27·5 lbs., while it never fell below 9·6 lbs.; and the average of the whole was as much as 18·1 lbs. per indicated horse power per hour."

It is quite true that in competitive trials at the Royal Agricultural Society's shows, the fuel consumption of the best portable engines, working under the most favourable conditions for a short time, is slightly below 2 lbs. per indicated horse power per hour; but this result can only be obtained by the most careful "nursing" of the fire by highly-paid skilled attendants, who salt the fire—so to speak—with a slight sprinkling of coal at very frequent intervals. In any case, we may safely say that, with gas power, the fuel consumption, under ordinary working conditions, is at least 50 per cent. less than with non-condensing steam-engines of equal power. With gas there is the further advantage that it can be conveyed to any part of the works without appreciable condensation; that separate engines can be used for different lines of shafting; and that any department working overtime can have its engine supplied with gas from a single generator. With steam, however, there is much condensation, if it is carried far, and much loss of fuel if a large boiler has to be fired to keep a small amount of shafting at work.

I have so far confined my remarks chiefly to the application of improved generator gas to motive power; and there is no doubt that the recent departure in this branch of mechanical science is one of great importance. I am, however, glad to add that a considerable advance has also been made in the use of this gas for heating of various kinds. At the Gloucester County Asylum it has been in daily use, for a variety of purposes, for about five years. All the kitchen work for the staff and inmates is done with it; and there is no ordinary fire in the kitchen. About 300 quartern loaves are baked with the gas every day, at a cost of about 1s. only for fuel. The gas is also employed for two 12-horse power (nominal) "Otto" engines, which pump water and drive a dynamo for electric lighting. The average cost of the gas is about 2d. per 1000 cubic feet, including wages, repairs, and all incidental expenses, or about 8d. for the equivalent of 1000 cubic feet of ordinary lighting gas. The anthracite costs about 13s. per ton. This gas is used on a large scale at the cocoa-works of Messrs. Van Houten and Son, of Messrs. Cadbury Bros., and of Messrs. Russ-Suchard and Co. Careful trials at the first-named works showed that the cost was under 1½d. per 1000 cubic feet or only 6½d. for the equivalent of 1000 cubic feet of the town lighting gas, with which comparative tests were made. The anthracite costs 16s. per ton. [The author gave the names of other firms who use the gas for industrial purposes.]

This gas is also used for melting type-metal, for heating bat-forms, and for other work in a hat manufactory. It has also been adopted for glass-blowing in an electric lamp factory, and for many other industrial purposes. I have, however, mentioned enough to

show that gas of this kind can be, and has been produced and applied successfully; and there is every reason to believe that its use will extend, especially as the gas-making apparatus is easy to work. I am not at liberty to state the annual saving effected by several firms who use the gas; but it is very considerable. The cost of the gas somewhat depends on that of the fuel and on the scale of working; but, speaking generally, the equivalent of 1000 cubic feet of ordinary lighting gas costs from 6d. to 1s. Compared with solid fuel, gas has certainly many advantages. It is under complete control; the heat derived from it can be kept constant or varied at will; it is comparatively easy to ensure complete combustion with but little chimney draught; it is more economical; and there is an entire absence of smoke. When solid fuel is used, it is necessary to introduce more than twice the quantity of air theoretically required for combustion, in order to drive away the products of combustion and to ensure a sufficiency of oxygen being brought into contact with the surfaces of the fuel. This large supply of air can only be drawn in by a strong chimney draught or other artificial means; and this causes a very rapid withdrawal of heat from the fire. Further than this, there is invariably some escape of smoke and partially burnt carbon in the form of carbonic oxide.

It is admitted that there is a demand for fuel gas; but for many purposes the ordinary lighting gas is too expensive, and the mere fact that it is made for lighting renders it so expensive. The percentage of illuminating constituents in coal gas is, indeed, very small; 20-candle power gas containing about 6½ per cent. and 16-candle power gas, as in London, containing only about 4 per cent. The remaining 93½ per cent. or 96 per cent. is composed of non-luminous heating gases; and the addition of the small proportion of illuminants adds greatly to the trouble and cost of producing the gas, and any great reduction of its present cost is improbable. It is therefore rational to suppose that for fuel purposes the lighting constituents should be dispensed with.

Assuming that we have a good and cheap fuel gas, there remains the question of how to apply it advantageously to whatever has to be heated; and here, I regret to say, difficulties often present themselves. It is one thing to have a combustible gas, but quite another to find suitable apparatus to be heated with it. Take, for instance, the case of a circulating boiler for heating a building. There is not one suitable for gas. There are a very few very ingenious little boilers for heating a small quantity of water; but as it would be too costly to heat a large one with town gas, there has hitherto been no inducement for boiler makers to trouble about a large size. In fact, the pioneer of gaseous fuel not only has to provide the gas, but in most cases he has also to devise the means of using it for the different purposes required. I have often been asked if generator or water gas can be used economically for heating ordinary steam-boilers; and I have always been obliged to answer in the negative. I have seen examples of nearly all the water-gas plants used in the United States and elsewhere, and I am aware that several attempts have been made to heat boilers with gas of this kind; but, so far as my knowledge goes, none of them have been successful from an economical point of view. In the first place, if the flames come in contact with the comparatively cool surface of the boiler, there is such a rapid withdrawal of heat that some of the gas does not attain the temperature necessary for its combustion. In the next place, there is no overlooking the fact that there must be a considerable loss of heat when the incandescent mass of fuel is enclosed in a gas generator, away from the boiler, instead of being on a grate within, or immediately under the boiler. I venture to think that the true solution of this important question is to be found in the production of gas within the boiler itself, and not in a separate apparatus. The mass of incandescent fuel would then assist, by conduction and radiation, in heating the boiler.

Reviewing the subject generally, I think it will be admitted that if the progress made has not been rapid, it has at least been sure; and, judging by experience gained in several countries, I find that more attention is given to gaseous fuel every year. It is a subject, too, that is now much better understood technically than it was only a few years ago; and my belief is that every year will see gas more largely used. Speaking more particularly of my own contribution to the subject, it is only right that I should acknowledge my indebtedness for the encouragement I met with when I read my first paper on the subject in 1881. It has often occurred to me since that my own experience in this respect may be taken as a fair illustration of one of the practical advantages of the British Association mootings to a beginner, whose success must depend to a great extent on the help he derives from useful criticism and advice.

Register of Patents.

CLEANING OR SEPARATING AMMONIACAL LIQUOR AND OTHER MATTERS FROM TAR.—Kriyenbnhl, J. G., Petersen, H. C., and Bruneister, C. C., of Copenhagen. No. 15,067; Nov. 4, 1887. [8d.]

This invention relates to the cleaning or separating of ammoniacal liquor and other matters from tar by a process so conducted as to render the tar fit to be used in tar distilleries or for technical or other purposes. The tar (containing ammoniacal liquor and other matters) is conducted into a tank so constructed that the tar leaves it at the pressure and temperature necessary for further treatment and allowing the ammoniacal liquor that may be separated to be taken off. The temperature for the tar in this vessel should be about 45° Celsius (113° Fahr.); but will, of course, vary with the different tars.

Fig. 1 represents a tank suited for the purpose. It is divided into compartments A, B, and C, with passages for the tar under one partition and over the other. The tar enters at the right, and passes down the compartment C under one partition, and between the steam coil D (by which the needful temperature is obtained), then up through the compartment B and over the other partition, and out at the left. G is an overflow-pipe, which maintains the level of the tar in the tank, and serves also to carry off the ammoniacal liquor therefrom. The tar passes out rid of part of the ammonia water, and is transferred into the revolving drum of a centrifugal machine or separator, which may be ordinary apparatus of this kind, but is preferably arranged as hereafter described. The tar has thus separated from it the ammoniacal liquor, which is drawn off from the drum through one pipe or outlet; whilst the pure tar is drawn off by another one.

In this treatment much of the impurities contained in the tar come against the wall of the drum, and may be removed by a special tube or outlet inserted for this purpose, or by making one of the other outlet tubes moveable from its normal position. If it be desired, however, that these impurities should remain in the tar, the revolving drum of the centrifugal machine may be so constructed that they are continuously drawn off along with the tar. Either before or after the treatment in the separator, the tar can be washed systematically with water, so that all the ammonia hydrate and other soluble matter is washed out; and, if desired, any water left from this process may be removed by subsequent treatment of the tar in the centrifugal machine.

A suitable washing vessel is shown in fig. 2. It is divided by horizontal plates, with passages past them alternately at opposite sides of the vessel. The tar enters at Y, and runs down over the plates, and leaves at the outlet Z. The water enters at V and leaves at W; so that the flow of the tar and water are in reverse directions.

Fig. 3 represents in vertical section a centrifugal machine or separator suited to the purposes of this invention. A is the outer casing, and B the revolving drum. C is the pipe and D the conical nozzle, through which the tar is fed into the drum B. There is a screwed rod, having at the bottom a valve to close, open, and regulate the passage through the conical nozzle; the rod being provided with a turning handle. When the machine is in operation, the ammonia water takes a position inward of the tar, as indicated at X and Y; X showing the ammonia water and Y the tar. The ammonia water is drawn off by the tube E; the tar being drawn off by the tubes F and G. When the machine is in full operation, these tubes are adjusted on the slide H, so that their inlet orifices are at the distance from the machine shown with regard to the tube F. Occasionally the tube G is screwed to the position shown in the illustration to draw off through it the layer of refuse and dirt which accumulates on the walls of the drum; and whilst this is being effected, only a small quantity of tar is fed into the drum. When the dirt is removed, the tube G is moved back, and fixed in a position like that of F, and the supply for tar to the drum is opened. The annular plate I should be fixed at a lower elevation (as shown) than is the case with ordinary centrifugal machines or separators.

GAS-ENGINES.—Sturgeon, T., of Ilkley. No. 16,309; Nov. 28, 1887 [8d.]

In patent No. 8879 of 1885, there is described a gas-engine having two pistons working in a cylinder, and in which the charge of mixed gas and air is ignited under compression between these pistons; the charge being supplied by means of another piston working in a cylinder at right angles to the working cylinder. The present patentee finds, however, that in small engines where the total amount of gas used is so slight that it is not so necessary to study economy in this respect, and where it is more essential to keep down the first cost, one of the

pistons in the working cylinder may be dispensed with, together with the beam and crank and other parts appertaining to it.

The present invention, therefore, consists in constructing a gas-engine as follows:—A working cylinder and a charging cylinder are used, placed at right angles to each other. There is one piston in the working cylinder, and one in the charging cylinder; and these pistons are connected to the same crank on the crank-shaft—one being connected direct, by means of a connecting-rod, and the other through the intervention of a connecting rod, sway-beam, and link. The action of the pistons will thus be such that one is moving through the middle or quickest part of its stroke, while the other is at about the end or slowest part. Thus, while the charging piston is at the quickest part of its inward stroke, rapidly driving a new charge of gas and air into the working cylinder, the working piston will be at about the end of its outward stroke, where it exposes the exhaust ports, and allows the products of combustion from the former charge to be expelled as they are displaced by the entrance of the new charge. In this engine one end of the working cylinder is closed, and the ports are so arranged that the new charge will be delivered as close as possible to the closed end; so that the new charge as it enters may sweep the products of combustion of the former charge before it. This is accomplished by making the port of a peculiar form. Thus, if the charging cylinder be horizontal, and the working cylinder vertical, the ports in the slide-valve, and in the face it works against, are made vertical; but as the port leading into the working cylinder approaches the interior, a twisted form is given to it, and not merely twisted, but also askew. Thus, as it opens into the working cylinder, it does so in a horizontal position close up to the cylinder cover.

REGENERATIVE GAS-LAMPS.—Kuhnt, A., and Deissler, R., of Berlin. No. 1134; Jan. 25, 1888. [11d.]

This invention (according to the patentees' statement) relates to gas-burners in which the gas is heated intensely, and freed from all impurities; and the air is heated thoroughly previous to being admitted before and behind the gas-flame. Moreover, the invention covers a device applied to the chimney-tube, having for its purpose to regulate the intensity of the annular flame.

As will be seen from the illustration, the gas chamber of the lamp consists of a plate provided with annular ribs, screwed on the bottom plate, also provided with ribs. The edges of the ribs bearing upon the opposite plates have serrations, through which the gas passes. The size of the serrations decreases from the inlet to the outlet of the gas chamber, so as to throttle the gas passing through, and heat it intensely. Besides this, "the gas leaves all impurities in the annular compartments formed by the ribs, and enters the burner-pipes thoroughly cleaned." An annular series of these burner-pipes are in connection with the last compartment of the gas chamber, as shown in the illustration. To the bottom plate of the chamber is attached the globe-holder A, the upper part of which forms the chamber for admitting the air to the flame. Between the cylindrical casing H, covering the burner and the globe-holder, is an annular space for the admission of air to the chamber L, whence the air is conducted to the upper part of the burner-pipes. A certain quantity of air passes between the burner-pipes and descends to the flame; while the remainder of it flows to the outer part of the flame. By this arrangement the air is intensely heated before passing to the flame. The centre of the apparatus is occupied by the chimney-tube R, to the lower end of which is attached a spout ending in a flange to spread the flame. The regulating-device, secured to the upper end of the chimney tube, is constructed as follows:—Semi-annular plates, supported by the chimney-tube, are connected to each other by means of a right and left hand screw, by turning which to the right or to the left, the plates are made to approach or to recede from each other. The aperture of the chimney-piece, and with it the intensity of the flame, is in this way increased or decreased. The ascending cross-plates disposed within the chimney-tube prevent any dust falling through the chimney-tube, and catch and collect the soot produced by the flame, as well as regulate the ascension of the combustion gases. The gas is conveyed to the gas chamber through the branch gas-pipe D (provided with a cut-off cock C), which runs down close to the chimney-tube R, in order to heat the gas before it is burned.

SEAL-PIPES FOR REDUCING THE PRESSURE IN GAS-RETORTS.—Palmer, R., of Sheffield. No. 2943; Feb. 28, 1888. [8d.]

This improved seal-pipe (shown in the accompanying drawing) can be attached to any shape of hydraulic main, and offers only a slight resistance to the discharge of gas from the retort. When the charge is in and the lids secured, the first discharge of gas displaces the water seal, allowing the gas to have free access to the hydraulic main D. As the discharge of gas becomes weaker from the retorts, the water seal returns to its position in proportion to the volume discharged; and when all the gas is given off from the retort, the seal becomes perfect against any gas backing down the ascension-pipe B.

It will also be seen, says the patentee, that the pipe C, inasmuch as it reduces the pressure on the retorts, prevents to a great extent blowing and leakage. With this seal-pipe the life and durability of the retorts will be prolonged; and the simplicity of the arrangement allows for increased capacity in the hydraulic main D—thereby giving a greater area for the flow of gas. These objects are attained by securing the seal-pipe C at one end to the vertical ascension-pipe B from the retorts, and the other to the hydraulic main D. The ordinary H pipe used between the ascension-pipe and the hydraulic main is entirely dispensed with. The pipe C is charged with water or the distillate or residuals from the carbonization of the coal in the hydraulic main.

GAS-ENGINES.—Nash, L. H., of Brooklyn, U.S.A. No. 10,350; July 17, 1888. [1s. 7d.]

By this invention the patentee claims certain improvements in gas-engines and in the mode of operating them. Space will not admit of a description of the author's claims, which are no less than 88 in number. The letterpress, which occupies 19 pages, is illustrated by six sheets of drawings, embracing 21 illustrations.

SILENCING THE EXHAUST FROM GAS-ENGINES.—Nobbs, F. G., of Exeter. No. 11,444; Aug. 8, 1888. [6d.]

This apparatus for rendering practically noiseless the exhaust from gas or petroleum engines consists of discharging the exhaust into a chamber specially devised for the purpose of deadening the sound thereof, instead of carrying it into pipes and discharging it at the side or on the top of the building where the engine is working. In this way a saving is effected in the exhaust-pipes, and the nuisance caused by the exhaust is abated.

The apparatus is intended to be either built in the ground, in any convenient position, or to stand upon the floor beside the engine; and the exhaust-pipe is arranged to terminate in a cone, for the purpose of dispersing the exhaust and the sound issuing therefrom when discharged. The chamber is filled with ordinary gas coke, or any other material sufficiently porous to absorb the vapour from the exhaust, enclosed in a wooden or other casing with a lattice-work ventilating cover.

REGENERATIVE GAS-LAMPS.—Butzke, F., of Berlin. No. 11,471; Aug. 9, 1888. [8d.]

This invention relates to gas-lamps with preparatory heating of the combustion air; the different arrangements being shown—figs. 1 and 2 being a vertical and a horizontal section of the lamp; and figs. 3 and 4, two modifications of it. The lamp is screwed on an ordinary gas-pipe by means of the burner P, to which the glass globe G is fastened. The heating chamber A, made from copper or other good heat-conducting material, is slanted off at the top in the direction of the air-inlets. It

is only used to heat the air passing round its outside—the air not circulating in the vessel A. It surrounds the chamber B, which is provided with slits in its outer circumference, through which the air is forced to pass. The air in the chamber is strongly heated by the burner, and causes a current of air to flow up in the direction of the arrows. This air is heated on its passage along the walls of the chamber; and after being heated, it flows out against the reflector F, by which it is guided to the flame. The glowing asbestos body K is held in the chimney R by hooks. The combustion gases in passing through the chimney impart most of their heat to the "glow body" K, which radiates its heat to the walls of the chimney, and by this means helps to heat the air. In the modified form (fig. 3), the bars for supporting the central division plate are dispensed with, which is an advantage, as they always throw a deep shadow; and the heating apparatus rests on the glass globe G. The "glow body" K is fitted with a conical flanged tube provided with holes; so that the heat has free access to the body K.

REGENERATIVE GAS-LAMPS.—Mücke, J., and Stern, W., of Berlin. No. 12,117; Aug. 22, 1888. [6d.]

The main object of this invention is to prevent the deposit of soot, rust, or impurities of any kind in the burner.

For this purpose, there is placed in the gas-tube a pipe of glass, porcelain, or any such material as is not liable to be oxidized or attacked at the heat required. The upper end of this tube is closed; but there are provided near the upper end lateral holes for the admission of gas. The inner pipe communicates with the burner; while the outer one is closed below. Any rust, &c., in the gas-pipe will thus fall outside the pipe, and not arrive in the burner. Furthermore, to keep the burner

clean from soot deposited from the flame, the air feed to the flame is so contrived that it does not mingle with the gas; and therefore the latter is not burnt until it arrives at a certain distance from the burner. In a burner with radial jets (as shown), this is done by placing above and below the jets, at a distance therefrom, raised ribs or flanges in such a manner that the air for feeding the flame is deflected outward thereby to mingle with the gas at a distance from the orifices of the burner. The manner of construction suitable for forming these flanges is illustrated. The part F with the upper flange is screwed on the base of the gas-inlet, and continued in the form of a pipe with lateral openings G into a chamber formed by the burner cylinder I, with orifices for the gas and the conical base E; forming (by its upper edge) the lower flange, and secured in place by a screw, which closes the lower end of the tube F.

GAS-STOVES.—Wilson, C. C., of Leeds. No. 12,283; Aug. 25, 1888. [6d.]

This invention has firstly for its object to arrange the gill-shaped flues of gas-stoves, that carry off the combustion gases to the chimney, to project forward from the face of the stove before passing back to the chimney outlet, in order to bring their heating surfaces (against which the air from the room passes) well forward into the room, so as to increase the heating power of the stove; and, secondly, to construct the Bunsen burners in such a manner that, for the purpose of reducing the heat, the outer jets of the burner can be entirely turned off, while the inner ones remain more or less full on, instead of regulating by turning the whole of the jets lower, whereby the possibility of the flame flashing back to the gas-inlet nozzle when the jets are turned down very low is avoided.

The heating arrangement of the stove may be of any known construction; but that described in patent No. 5209 of 1884 is preferred. Instead, however, of providing it with gill-shaped flues leading up directly from the top of the stove, the top is closed over, as shown; and in front of the upper part a casing is formed, constituting a number of gill-shaped flues B that project beyond the face of the stove, and, after rising a certain distance, curve over the top to the back, where they unite in a common chamber C, which communicates with the chimney. The flues, consequently, afford heating surfaces that project beyond the face of the stove, against which surfaces the air circulating round the back of the stove passes on its way into the room.

THE RELATIVE ECONOMY OF GAS-ENGINES AND HYDRAULIC POWER.

SIR,—In reference to the article in your issue of the 30th ult. (p. 762), on the "Economy of Ordinary Coal Gas as a Motive Power," I wish to point out that the figures quoted from my paper published in the Transactions of the Institution of Civil Engineers, and from the remarks made during the discussion, are hardly comparable. I explained in the paper the reasons for the apparently high average charges for the hydraulic power. These average figures do not correspond to the cost per indicated horse power per hour of running the engines for a few hours on a brake. The power to be adopted in any given case will, on the average, be settled by what would be the total average cost of running the machinery with the different systems of power available. For the special objects which the hydraulic power companies have been established to promote, both theory and experience seem conclusively to show that hydraulic power is the cheapest and best.

It would be traversing the ground covered by my paper to enter more fully into this question; but, in confirmation of my views, perhaps I may be permitted to add that there are now nearly 800 machines regularly working from the mains of the London Hydraulic Power Company, all set to work during the last five years, in competition with gas, steam, and other power. These machines are mostly for lifting and other intermittent work. On the other hand, the use of gas-engines for the general driving of machinery has hardly been affected by the Company's operations.

I do not wish in any way to detract from the great merits of the gas-engine; but it appears to me that to advocate its use for such purposes as pumping water for working lifts, in competition with direct hydraulic pressure, is not likely to be a successful policy.

THE MIDDLEMAN.

SIR,—It is greatly to be regretted that a public question of so much importance as the coal supply to our gas and other corporations should be overlaid with personal and side issues, such as those raised in your "Correspondence" and other columns on the 30th ult. We will dismiss these personal attacks, and the inferences it is desired should be drawn from them, by quoting a reflection of Hamlet: "Be thou chaste as ice, as pure as snow, thou shalt not escape calumny."

Calumny requires a victim, and in this instance the calumniator has selected the poor unoffending middleman. We should think that he is himself greatly astonished at the success that has attended his bold venture, seeing that he has drawn no less distinguished a person than the President of The Gas Institute. Because, forsooth, he has had experience of the smartness of a "very clever fellow"—whom, surely, he ought to have known, and been able to cope with, unless his position enormously overrates him—he denounces a whole class of men, as honourable in character as Mr. Woodall himself, and without whom commercial life would undergo a great change, and that not for the better.

Mr. Woodall writes: "On one occasion, I found that our intimate friend had been paying a commission to a casual acquaintance on coals supplied to me, and that naturally enough he had given me credit for having shared in the plunder." It is much to be regretted that the contractor, being an "intimate friend" of Mr. Woodall's, should not have thought and known differently than to have given him credit for sharing any plunder. Mr. Woodall informs us, in the other case of which he writes, that it was a colliery who was paying a commission to the "very clever fellow;" but he does not state if his "intimate friend" is a colliery owner, colliery representative, or a middleman. Pray has Mr. Woodall never dealt with a middleman?

The commission system is hateful, and deserving the severest condemnation. But to try to fasten the responsibility for that system upon the middleman is to take a very narrow, one-sided, and unjust view of the question. Mr. Woodall, in the plenitude of his narrowness, suggests that there is no need of a negotiator, and that a gas company "is sure of being supplied with what it bargains for when dealing with the colliery direct," who, *volens volens*, becomes the negotiator that Mr. Woodall so unceremoniously dismisses as a superfluity. Nay, more, there stands another "negotiator," the representative of the colliery owner, who will have his voice in the making of contracts. Does Mr. Woodall think that these "negotiators" everywhere will be pure, and stainless from the guilt of bribes? His faith is large and strong; but his knowledge is sadly imperfect. It is not long since, Sir, that an advertisement appeared in your JOURNAL from several manufacturers of gas-meters, to the effect that in future they would not allow any commissions on their transactions, which one may take to be clear proof that commissions had been previously paid.

The middleman, if upright and honest—and to insinuate that the class to which he belongs is not honest or upright is a foul calumny—by reason of the competition that he encounters, is bound to supply the article for which he tenders, and becomes a buffer against any collusion between the agents of the two contracting parties.

Has Mr. Woodall forgotten the "Salford Scandal"? There the system which he appears to desiderate was in full and perfect working. No middleman there stood between the Corporation and certain collieries; but two well-known collieries were found to have paid large sums by way of corrupt commissions which were negotiated through their own representatives.

The recent colliery strikes will afford to a reasonable mind the most conclusive argument in favour of the "middleman." A contract entered into with a particular colliery is absolutely at the risk of a gas company or corporation. A strike is fatal. The system admits of no elasticity. We have ourselves, within the last few weeks, had applications for several thousand tons of gas coal from gas undertakings throughout England, in order to cover deficient supply due to the suspension of work at particular collieries. Fortunately for these applicants, "the happy day" has not yet come when the free and independent middleman is no longer to be found in the land, and when the

"incorruptible" gas engineer, and the equally "incorruptible" corporation official, will be left to go their way practically unchecked and uncontrolled. Until the law of supply and demand is regulated, the middleman will, we feel confident, be able to prove his *raison d'être*; and therefore, thanking you, in anticipation, for inserting this letter, we will now dismiss the chimera of his suggested abolition.

THE MIDLAND COAL AND CANNEL COMPANY,
Nottingham, Nov. 5, 1888. WORTHINGTON CHURCH.

WATER BY MEASURE.

SIR,—In reply to "True Measure," in the last number of the JOURNAL, I beg to state that I am acquainted with three "low-pressure" water-meters—viz., Parkinson's, Cowan's, and the Bascul. But why these meters or any others ought not to be used for a domestic supply, I have already stated in the article referred to.

As a further objection to the use of low-pressure meters, it is certainly a most inconvenient position to fix a meter over the cistern. My experience is that in modern towns, they are placed in the roof; and it being necessary to read water-meters once a month, and to be constantly repairing and changing them I think if placed there they would be voted a great nuisance by most householders, and condemned by all water inspectors, as well as imposing an unnecessary expense on the companies for inspection, reading, and repairs.

I wait for "True Measure" to explain why his low-pressure meter ought to be used and fixed over a cistern? What is the name of the meter? And why is such a meter and position superior to the present class of meters and methods of fixing? Also, how will he get over the difficulty of the new "fad" demanded by the medical profession, of connecting the drinking-water tap direct from the main? Then there is the garden supply for a large number of houses, which must be delivered under pressure, and would require another class of meter.

I quite concur, Sir, in your statement that cisterns are a necessity. This was sufficiently explained in the JOURNAL for Dec. 20, 1887 (p. 1090).

I am exceedingly obliged to Mr. R. F. Grantham for his kind remarks, and his concurrence in the main objects of the paper in question. It is gratifying to know that such an authority is entirely opposed to a supply of water by meter for domestic purposes.
